Field Description	Type	Defaults	Pop-Up
Special chainage files	column header		size menu for the fields -*.spc files

list of files of special chainages for creating sections at.

Comment	column header		
			<i>comment to add to the end of the line. In the file, the comment will be preceded by //.</i>

Wild card	input	*.spc	
			<i>the wild card used for pop-ups in the special chainage files fields.</i>

OK/Apply	button		
			<i>OK stores the values in the fields and removes the panel. Apply stores the values and leaves the panel on the screen.</i>

Please continue to the next section “Hinge Modifiers” .

Hinge Modifiers

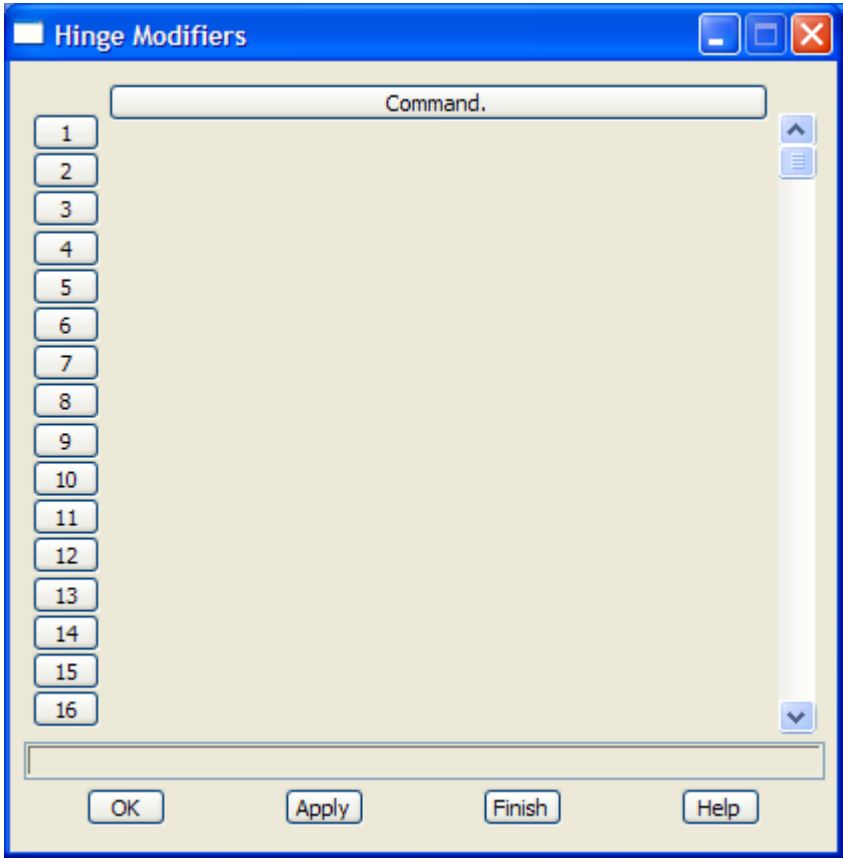

mtf_edit_hinge_modifiers

The **hinge string** is selected using the hinge panel field in either the **apply template function** or **apply templates function** panels.

Hinge modifiers are used to **modify** the position of the point on the hinge string that the template is applied to (the **hinge point**).

Selecting Hinge from the MTF Edit menu brings up the **Hinge Modifiers** panel.

The **Hinge Modifiers** panel consists of a scrolling command fields and an **OK** or **Apply** button to record the results.

The **width** of the command area in the **Hinge Modifiers** panel is controlled by the environment variable **DEFAULT_TABLE_WIDTH_4D**.

The **commands** in the hinge modifier field can be **offset**, **height**, **offset to string**, **heights to string**, **coord to string**, **no hinge** and **comment**.

mtf_edit_hinge_create

If the command line is **empty**, clicking LB in the command line will bring up the Create menu which contains all the available hinge commands.

adjust offset of hinge string
 " height " " "
 use offset to a string
 use height from a string
 take coords from a string
 stop the apply
 comment

Selecting a menu item will bring up an associated panel which displays the information required for the hinge command.

When the panel is filled in and **OK** or **Apply** selected, the panel information is written out to the command line in the correct format for that hinge command.

If the command line is **not empty**, clicking LB in the command line will bring up the associated panel for the hinge command in the command line.

The information in the panel can be modified and if **OK** or **Apply** is selected, the modified panel information is written out to the command line in the correct format for that hinge command.

Each of the panels created by selecting the command from the Create menu, will now be described.

The typed form of the command will be given in the section "Hinge Modifier File Format" and an example is given in the section "A Hinge Modifier Example"

For documentation on the option on the Hinge modifier Create menus:

for	<i>Offset</i> ,	go to the section "Offset"
	<i>Height</i>	"Height"
	<i>Offset to string</i>	"Offset to String"
	<i>Height to string</i>	"Height to String"
	<i>Coord to sting</i>	"Coord to String"
	<i>No hinge</i>	"No Hinge"
	<i>Comment</i>	"Comment"

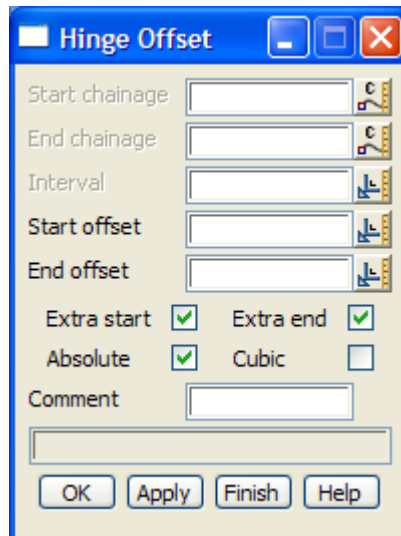

[mtf_edit_hinge_hinge_offset](#)

Offset

The **offset** modifier will move the hinge point a given offset distance (perpendicular to the reference string) from its current plan position. A positive offset is to the right of the hinge string and a negative offset to the left.

Selecting the offset option brings up the **hinge offset** panel

The fields and buttons used in this panel have the following functions.

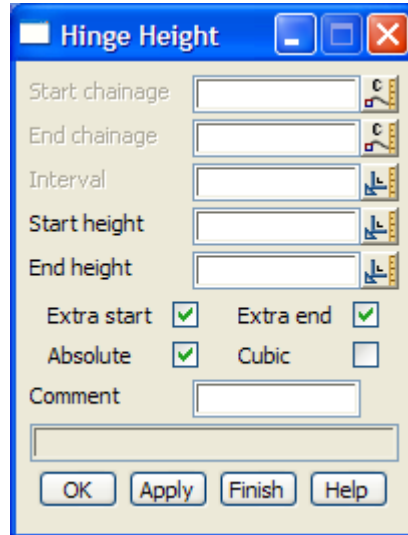

Field Description	Type	Defaults	Pop-Up
Start/End chainage <i>start/end chainages for modifying the offset from the hinge string.</i>	input		measures menu
Interval <i>if non blank, the interval to use to create cross sections and strings over the given chainage range. If blank, the Section separation value from the Apply Many panel is used.</i>	input		
Start/End offset <i>start/end offset.</i>	input		measures menu
Extra start/end <i>if tick, add an extra x-section 0.1 mm before the start/end chainage.</i>	tick box	tick	
Absolute <i>if tick, the offset is set to the values given in the start and end value fields. if not tick, the values given in the start and end value fields are added to the existing offsets.</i>	tick box	tick	
Cubic <i>if tick, the offset is varied as a reverse cubic between the start and end chainages. if not tick, the offset is varied linearly between the start and end chainages.</i>	tick box		
Comment <i>comment to add to the end of the line. In the file, the comment will be preceded by //.</i>	input		
OK/Apply <i>OK stores the values in the fields and removes the panel. Apply stores the values and leaves the panel on the screen.</i>	button		

[mtf_edit_hinge_hinge_height](#)

Height

The **height** modifier varies the height of the hinge point between the given chainages.

Selecting the height option brings up the **hinge height** panel

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Start/End chainage <i>start/end chainages for modifying the height of the hinge string.</i>	input		measures menu
Start/End height <i>start/end height.</i>	input		measures menu
Interval <i>if non blank, the interval to use to create cross sections and strings over the given chainage range. If blank, the Section separation value from the Apply Many panel is used.</i>	input		
Extra start/end <i>if tick, add an extra x-section 0.1 mm before the start/end chainage.</i>	tick box	tick	
Absolute <i>if tick, the height is set to the values given in the start and end value fields. if not tick, the values given in the start and end value fields are added to the existing heights.</i>	tick box	tick	
Cubic <i>if tick, the height is varied as a reverse cubic between the start and end chainages. if not tick, the height is varied linearly between the start and end chainages.</i>	tick box		
Comment <i>comment to add to the end of the line. In the file, the comment will be preceded by //.</i>	input		
OK/Apply <i>OK stores the values in the fields and removes the panel. Apply stores the values and leaves the panel on the screen.</i>	button		

[mtf_edit_hinge_hinge_offset_to_string](#)

Offset to String

Selecting the offset to string option brings up the **hinge offset to string** panel

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Start/End chainage <i>if non blank, start/end chainages for modifying the offset of the hinge string. If blank, the modifier is applied for the length of the selected string.</i>	input		measures menu
Interval <i>if non blank, the interval to use to create cross sections and strings over the given chainage range. If blank, the Section separation value from the Apply Many panel is used.</i>	input		
String <i>select string to use for defining offset from hinge.</i>	string-select		
Extra start/end <i>if tick, add an extra x-section 0.1 mm before the start/end chainage.</i>	tick box	tick	
Comment <i>comment to add to the end of the line. In the file, the comment will be preceded by //.</i>	input		
OK/Apply <i>OK stores the values in the fields and removes the panel. Apply stores the values and leaves the panel on the screen.</i>	button		

[mtf_edit_hinge_hinge_height_to_string](#)

Height to String

The height of the hinge point can also be specified by **taking the height from another 12d Model string.**

Selecting the height to string option brings up the **hinge height to string** panel

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Start/End chainage	input		measures menu

*if **non blank**, start/end chainages for modifying the height of the hinge string.
If **blank**, the modifier is applied for the length of the selected string.*

Interval	input		
-----------------	-------	--	--

*if **non blank**, the interval to use to create cross sections and strings over the given chainage range.
If **blank**, the Section separation value from the **Apply Many** panel is used.*

String	string-select		
---------------	---------------	--	--

select string to use for defining height of hinge.

Extra start/end	tick box	tick	
------------------------	----------	------	--

*if **tick**, add an extra x-section 0.1 mm **before** the start/end chainage.*

Comment	input		
----------------	-------	--	--

comment to add to the end of the line. In the file, the comment will be preceded by //.

OK/Apply	button		
-----------------	--------	--	--

***OK** stores the values in the fields and removes the panel.
Apply stores the values and leaves the panel on the screen.*

[mtf_edit_hinge_hinge_coord_to_string](#)

Coord to String

The **coord** modifier is used to replace the x, y and z position of the hinge point by the x, y and z position of **another 12d Model string** between given chainages. Hence **coord** replaces the hinge string by another string between the given chainages.

Selecting the Coord to string option brings up the **hinge coord to string** panel

The fields and buttons used in this panel have the following functions.

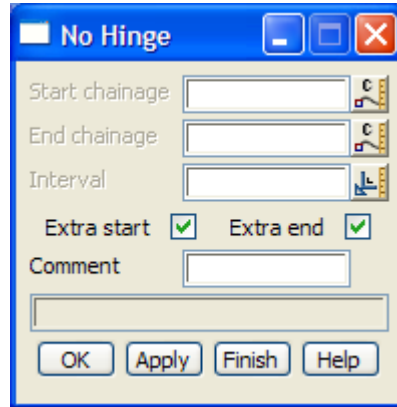

Field Description	Type	Defaults	Pop-Up
Start/End chainage	input		measures menu
<i>if non blank, start/end chainages for modifying the coordinates of the hinge string.</i>			
<i>If blank, the modifier is applied for the length of the selected string.</i>			
Interval	input		
<i>if non blank, the interval to use to create cross sections and strings over the given chainage range.</i>			
<i>If blank, the Section separation value from the Apply Many panel is used.</i>			
String	string-select		
<i>select string to use for defining the coordinates of the hinge string.</i>			
Extra start/end	tick box		
<i>if tick, add an extra x-section 0.1 mm before the start/end chainage.</i>			
Comment	input		
<i>comment to add to the end of the line. In the file, the comment will be preceded by //.</i>			
OK/Apply	button		
<i>OK stores the values in the fields and removes the panel.</i>			
<i>Apply stores the values and leaves the panel on the screen.</i>			

[mtf_edit_hinge_no_hinge](#)

No Hinge

The **nohinge** modifier is used to **stop** the hinge string (and hence the apply) between given chainages. This will leave a gap in the strings created by the apply between the given chainages.

Selecting the no hinge option brings up the **no hinge** panel

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Start/End chainage <i>start/end chainages to stop the apply.</i>	input		measures menu
Interval <i>if non blank, the interval to use to create cross sections and strings over the given chainage range. If blank, the Section separation value from the Apply Many panel is used.</i>	input		
Extra start/end <i>if tick, add an extra x-section 0.1 mm before the start/end chainage.</i>	tick box		
Comment <i>comment to add to the end of the line. In the file, the comment will be preceded by //.</i>	input		
OK/Apply <i>OK stores the values in the fields and removes the panel. Apply stores the values and leaves the panel on the screen.</i>	button		

mtf_edit_hinge_hinge_comment

Comment

The **comment** option inserts a comment line.

Selecting the Comment option brings up the **Hinge Comment** panel

The fields and buttons used in this panel have the following functions.

Comment <i>comment line. In the file, the comment will be preceded by //.</i>	input		
OK/Apply <i>OK stores the values in the fields and removes the panel.</i>	button		

Apply stores the values and leaves the panel on the screen.

Please continue to the next section “Template Modifiers” .

Template Modifiers

The standard **many templates file (mtf)** is used to define what templates are used on either side of the hinge and defines where the templates stop and start, and allows for linearly interpolation between two templates over a chainage range. The information is given in the `left_side` and `right_side` blocks of information in the **many templates file** and/or the templates section of the mtf edit menu.

Template modifiers are used to **modify** the definitions in the `left_side` and `right_side` definitions and are given as **left_side_modifier** and **right_side_modifier** in the mtf file and/or the modifiers section of the mtf edit menu.

That is, for the left side say, the application of templates is first defined in the `left_side` command section and then **modified** by commands in the `left_side_modifier` section. In this case, the `left_side` set must be before the `left_side_modifier` in the many templates file.

However, the modifiers **also include** commands to **insert** and **remove** template links independently of whether a template has been used or not.

Hence the left side modifiers can be **self contained** without needing a `left_side` command.

Similarly for the right side.

The template modifiers can be used to

- insert a fixed, cut or fill link
- remove a fixed, cut or fill link

and change the

- width of a fixed link
- height of a fixed link
- xfall of a fixed link
- width of a variable cut link
- height of a variable cut link
- slope of a variable cut link

- width of a variable fill link
- height of a variable fill link
- slope of a variable fill link

- width of the final link
- cut slope of the final link
- fill slope of the final link

Most of the modifiers have a common methodology:

- (a) a link from a template (referenced by its name from the template definition) is created, removed or modified between a start and end chainage.
- (b) values being modified are given for the start chainage and the end chainage. How the values are interpreted depends on other parameters for the command.
- (c) more than one modifier may exist for a link at a given chainage and are applied in the order that they appear.
- (d) if no modifier exists for a link at a given chainage, the link reverts back to the template definition given by `left_side` or `right_side`

Notes

1. When a fixed link is defined, it is given as two of the three variables width, height and xfall. Only the two variables used to define the link can be changed by template modifiers.
2. Similarly, when a variable cut or fill link is defined, it is given as two of the three variables width, height and slope. Only the two variables used to define the link can be changed by

template modifiers.

Please continue to the next section “Template Modifiers in MTF Edit” .

Template Modifiers in MTF Edit

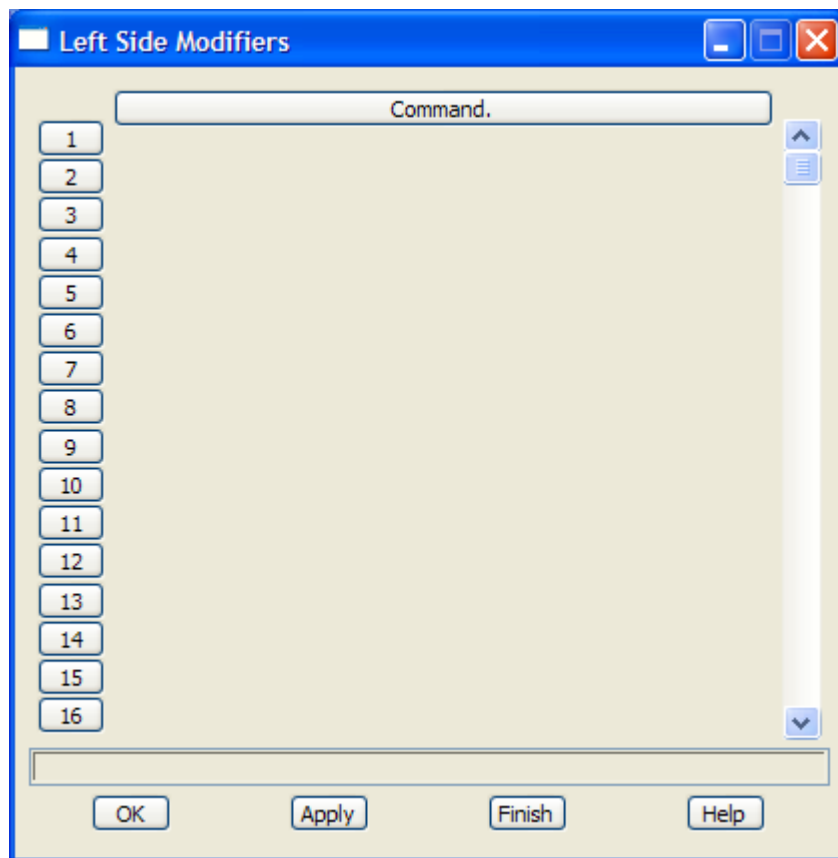

`mtf_edit_modifiers`

The modifiers walk-right brings up the modifiers menu with options to modify the left_side and right_side sections of the mtf file.

The left side modifier option will be described in detail. The right side is exactly the same so will not be described.

Selecting left side from the mtf edit=>left side menu brings up the **left side modifiers** panel.

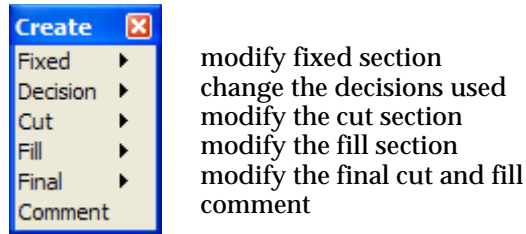

The **left side modifiers** panel consists of a scrolling command fields and a **OK** or **Apply** button to record the results.

The **width** of the command area in the **Left Side Modifiers** panel is controlled by the environment variable `DEFAULT_TABLE_WIDTH_4D`.

`mtf_edit_modify_create`

If the command line is **empty**, clicking LB in the command line will bring up the Create menu which contains all the available hinge commands.

Selecting a menu item will bring up an associated panel which displays the information required for the modifier command.

When the panel is filled in and **OK** or **Apply** selected, the panel information is written out to the command line in the correct format for that modifier command.

If the command line is **not empty**, clicking LB in the command line will bring up the associated panel for the modifier command in the command line.

The information in the panel can be changed and if **OK** or **Apply** is selected, the changed panel information is written out to the command line in the correct format for that modifier command.

Each of the panels created by selecting a command from the Create menu, will now be described.

The command itself, and its typed format, has already been described in the previous section on the template modifier file format.

The typed format of the command will be given for each panel.

For documentation on the option on the Left/Right Side modifier Create menu:

for	<i>Fixed</i> ,	go to the section "Fixed Modifiers"
	<i>Decision</i>	"Decision"
	<i>Cut</i>	"Cut Modifiers"
	<i>Fill</i>	"Fill Modifiers"
	<i>Final</i>	"Final Modifiers"

The text form of the Left/Right side template modifiers is given in the section "Template Modifiers File Format"

Please continue to the next section "Fixed Modifiers".

Fixed Modifiers

mtf_edit_modify_create_fixed

The fixed walk-right brings up the fixed menu with options to modify the fixed links of the template.

To go straight to the documentation on each of the options on the Fixed modifier menu:

For	<i>Insert</i> ,	go to the section "Fixed Insert" .
	<i>Remove</i>	"Fixed Remove"
	<i>Width/Height</i>	"Fixed Width and Height"
	<i>Xfall from link</i>	"Fixed Xfall"
	<i>Xfall CRC</i>	"Fixed Xfall CRC"
	<i>Width/Height/Xfall from link</i>	"Fixed Width, Height and Xfall from a Link"
	<i>Width/Height/Xfall to string</i>	"Fixed Width, Height and Xfall to a String"
	<i>Height/Xfall to tin</i>	"Fixed Height to Tin and Xfall to Tin"
	<i>Width/Height/Xfall to 2 strings</i>	"Fixed Width, Height and Xfall between Two Strings"

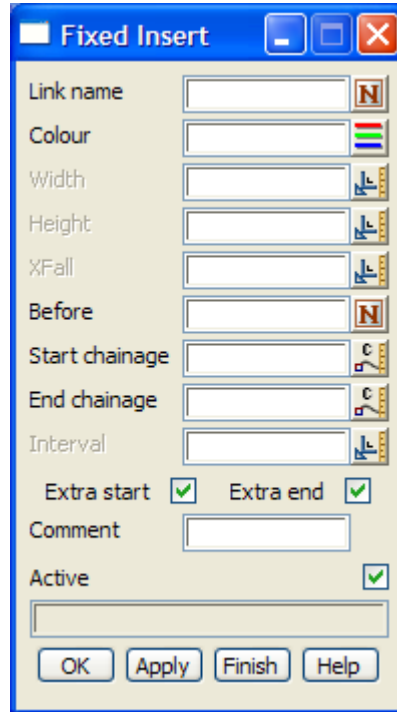

Each of the options from this menu will now be described.

[mtf_edit_modify_fixed_insert_](#)

Fixed Insert

Fixed links can be inserted by specifying either width and height, width and xfall, or height and xfall.

Selecting the insert option brings up the **fixed insert** panel

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Link name <i>name of the link to create.</i>	input		select name menu
Colour <i>colour of the link being created.</i>	input		available colours
Width /height/xfall <i>width/ height/ crossfall of the link being created - only use two of the three.</i>	input		measures menu
Before <i>if non-blank, the name of the string to insert the new string before. If blank, the link is appended to the end of the fixed part of the template.</i>	input		select name menu
Start/End chainage <i>start/end chainages for inserting the new template link.</i>	input		measures menu
Interval <i>if non blank, the interval to use to create cross sections and strings over the given chainage range. If blank, the Section separation value from the Apply Many panel is used.</i>	input		
Extra start/end <i>if tick, add an extra x-section 0.1 mm before the start/end chainage.</i>	tick box		
Comment <i>comment to add to the end of the line. In the file, the comment will be preceded by //.</i>	input		
Active <i>if tick, use this modifier. if not tick, don't use this modifier.</i>	tick box	tick	

OK/Apply button

OK stores the values in the fields and removes the panel.

Apply stores the values and leaves the panel on the screen.

[mtf_edit_modify_fixed_remove](#)

Fixed Remove

Fixed links can be deleted between given chainages by using the **fixed remove** option.

Selecting the remove option brings up the **fixed remove** panel

The fields and buttons used in this panel have the following functions.

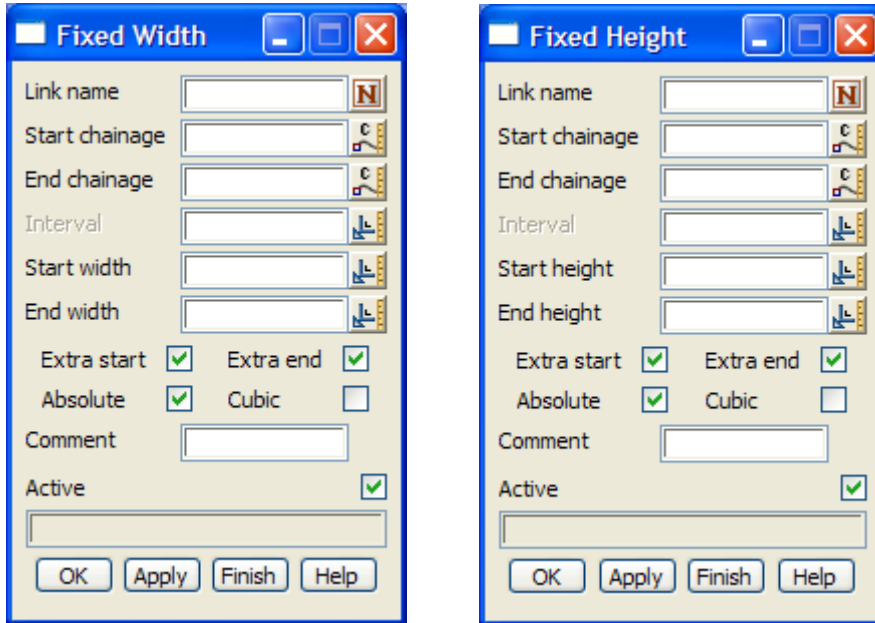

Field Description	Type	Defaults	Pop-Up
Link name <i>name of the link to removed.</i>	input		select name menu
Start/End chainage <i>start/end chainages for removing the template link.</i>	input		measures menu
Interval <i>if non blank, the interval to use to create cross sections and strings over the given chainage range. If blank, the Section separation value from the Apply Many panel is used.</i>	input		
Extra start/end <i>if tick, add an extra x-section 0.1 mm before the start/end chainage.</i>	tick box		
Comment <i>comment to add to the end of the line. In the file, the comment will be preceded by //.</i>	input		
Active <i>if tick, use this modifier. if not tick, don't use this modifier.</i>	tick box	tick	
OK/Apply OK stores the values in the fields and removes the panel. Apply stores the values and leaves the panel on the screen.	button		

[mtf_edit_modify_fixed_width](#) [mtf_edit_modify_fixed_height](#)

Fixed Width and Height

The **width** modifier is used to modify the width of fixed links originally defined by width. The **height** modifier is used to modify the height of fixed links originally defined by height.

Selecting the **width** and **height** option brings up the **fixed width** and **fixed height** panels respectively.

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Link name <i>name of the link to modify.</i>	input		select name menu
Start/End chainage <i>start/end chainages for modifying the template link.</i>	input		measures menu
Interval <i>if non blank, the interval to use to create cross sections and strings over the given chainage range. If blank, the Section separation value from the Apply Many panel is used.</i>	input		
Start/End width/height <i>start/end width/height for modifying the template link.</i>	input		measures menu
Extra start/end <i>if tick, add an extra x-section 0.1 mm before the start/end chainage.</i>	tick box		
Absolute <i>if tick, the width/height is set to the values given in the start and end value fields. If not tick, the values given in the start and end value fields are added to the existing widths/heights.</i>	tick box	tick	
Cubic <i>if tick, the width/height is varied as a reverse cubic between the start and end chainages. If not tick, the width/height is varied linearly between the start and end chainages.</i>	tick box		
Comment <i>comment to add to the end of the line. In the file, the comment will be preceded by //.</i>	input		

Active tick box tick

*if tick, use this modifier.
if not tick, don't use this modifier.*

OK/Apply button

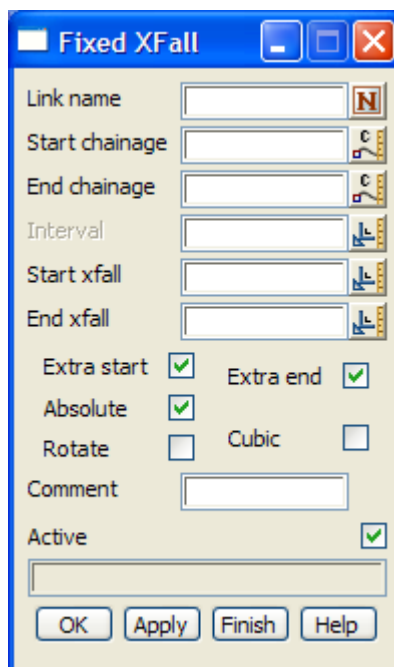

OK stores the values in the fields and removes the panel.
Apply stores the values and leaves the panel on the screen.

mtf_edit_modify_fixed_xfall

Fixed Xfall

The **xfall** modifier is used to modify the cross fall of fixed links originally defined by cross fall.

Selecting the xfall option brings up the **fixed xfall** panel

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Link name <i>name of the link to modify.</i>	input		select name menu
Start/End chainage <i>start/end chainages for modifying the template link.</i>	input		measures menu
Interval <i>if non blank, the interval to use to create cross sections and strings over the given chainage range. If blank, the Section separation value from the Apply Many panel is used.</i>	input		
Start/End xfall <i>start/end crossfall for modifying the template link.</i>	input		measures menu
Extra start/end <i>if tick, add an extra x-section 0.1 mm before the start/end chainage.</i>	tick box		

Absolute tick box tick

*if tick, the xfall is set to the values given in the start and end xfall fields.
if not tick, the values given in the start and end xfall fields are added to the existing xfall.*

Cubic and Rotate tick boxes:

*Only none or one of **Cubic** and **Rotate** can be set to **tick**.
The **default** is none - that is, **neither is ticked** and in the default case, the crossfall is varied **linearly with respect to crossfall** between the start and end chainages.*

Cubic tick box

if tick, the crossfall is varied as a reverse cubic between the start and end chainages.

Rotate tick box

*if tick, the xfall is varied linearly **with respect to the angle**, between the start and end chainages.*

Comment input

comment to add to the end of the line. In the file, the comment will be preceded by //.

Active tick box tick

*if tick, use this modifier.
if not tick, don't use this modifier.*

OK/Apply button

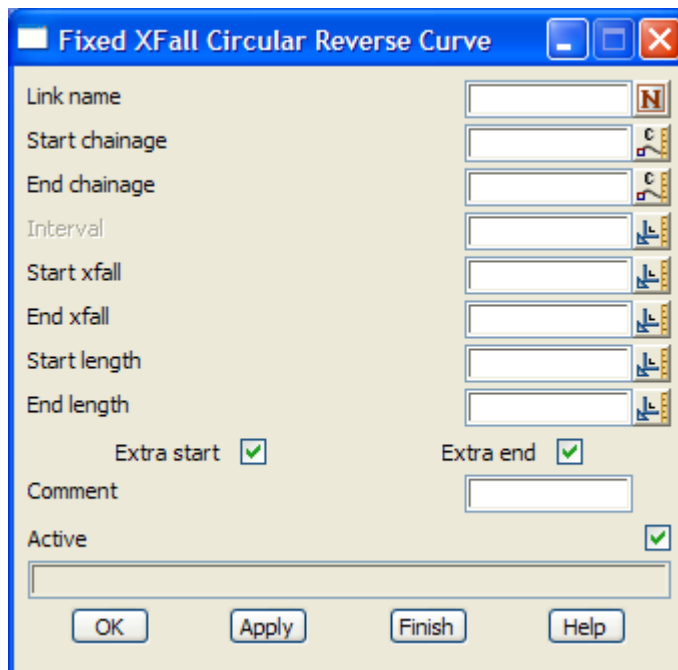

*OK stores the values in the fields and removes the panel.
Apply stores the values and leaves the panel on the screen.*

[mtf_edit_modify_fixed_xfall_0](#)

Fixed Xfall CRC

The **xfall_crc** modifier is used to modify the cross fall of fixed links originally defined by **xfall** and uses the **circular reverse curve** formula to modify the cross fall.

Selecting the xfall crc option brings up the **fixed xfall circular reverse curves** panel

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Link name <i>name of the link to modify.</i>	input		select name menu
Start/End chainage <i>start/end chainages for modifying the template link.</i>	input		measures menu
Interval <i>if non blank, the interval to use to create cross sections and strings over the given chainage range. If blank, the Section separation value from the Apply Many panel is used.</i>	input		
Start/End xfall <i>start/end crossfall for modifying the template link.</i>	input		measures menu
Start/End length <i>start/end length for circular arcs.</i>	input		measures menu
Extra start/end <i>if tick, add an extra x-section 0.1 mm before the start/end chainage.</i>	tick box		
Comment <i>comment to add to the end of the line. In the file, the comment will be preceded by //.</i>	input		
Active <i>if tick, use this modifier. if not tick, don't use this modifier.</i>	tick box	tick	
OK/Apply <i>OK stores the values in the fields and removes the panel. Apply stores the values and leaves the panel on the screen.</i>	button		
mtf_edit_modify_fixed_width_from_link mtf_edit_modify_fixed_height_from_link mtf_edit_modify_fixed_xfall_from_link			

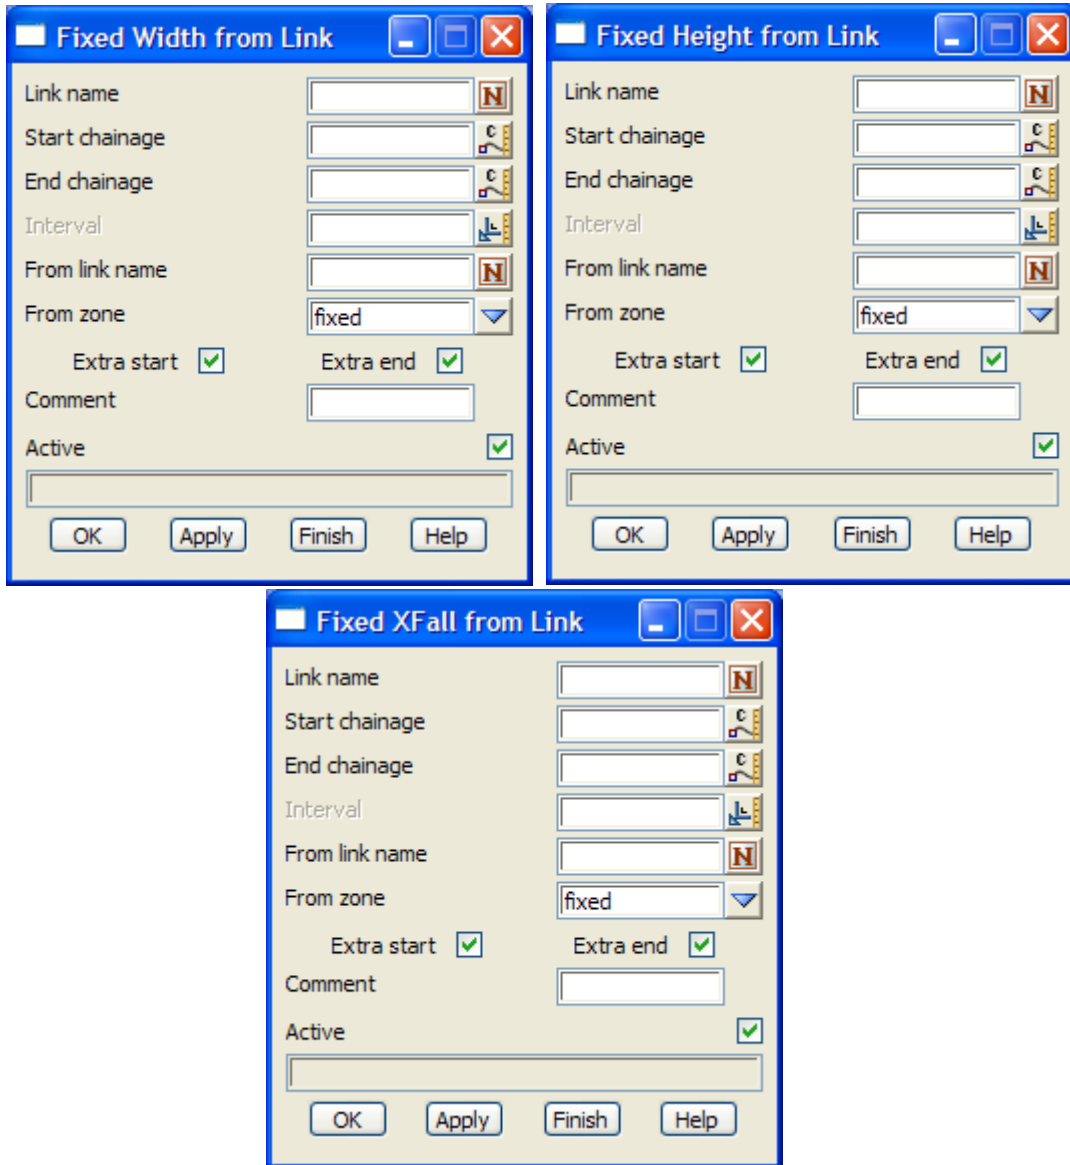

Fixed Width, Height and Xfall from a Link

The **width from link** modifier is used to modify the width of fixed links originally defined by width to be the same width as another link. That is, the width of the link is a **copy** of the **width** of another link.

The **height from link** modifier is used to modify the height of fixed links originally defined by height to be the same height as another link. That is, the height of the link is a **copy** of the **height** of another link.

The **xfall from link** modifier is used to modify the cross fall of fixed links originally defined by xfall to be the same xfall as another link. That is, the cross fall of the link is a **copy** of the **cross fall** of another link. The link to copy cross fall from can be defined in terms of cross fall or slope. If the link to copy is defined by slope, then the cross fall is calculated to match the slope.

Selecting the width from link, height from link or xfall from link option brings up the **fixed width from link**, **fixed height from link** and **fixed xfall from link** panels respectively.

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Link name <i>name of the link to modify.</i>	input		select name menu
Start/End chainage <i>start/end chainages for modifying the template link.</i>	input		measures menu
Interval <i>if non blank, the interval to use to create cross sections and strings over the given chainage range. If blank, the Section separation value from the Apply Many panel is used.</i>	input		
From link name <i>template link to take width/height/xfall from.</i>	input		select name menu
From zone <i>zone that the template link to take width/height/xfall from, comes from.</i>	input	fixed	fixed, cut, fill

Extra start/end	tick box	
	<i>if tick, add an extra x-section 0.1 mm before the start/end chainage.</i>	
Comment	input	
	<i>comment to add to the end of the line. In the file, the comment will be preceded by //.</i>	
Active	tick box	tick
	<i>if tick, use this modifier.</i>	
	<i>if not tick, don't use this modifier.</i>	
OK/Apply	button	
	<i>OK stores the values in the fields and removes the panel.</i>	
	<i>Apply stores the values and leaves the panel on the screen.</i>	
	<i>mtf_edit_modify_fixed_width_to_string mtf_edit_modify_fixed_height_to_string</i>	
	<i>mtf_edit_modify_fixed_xfall_to_string</i>	

Fixed Width, Height and Xfall to a String

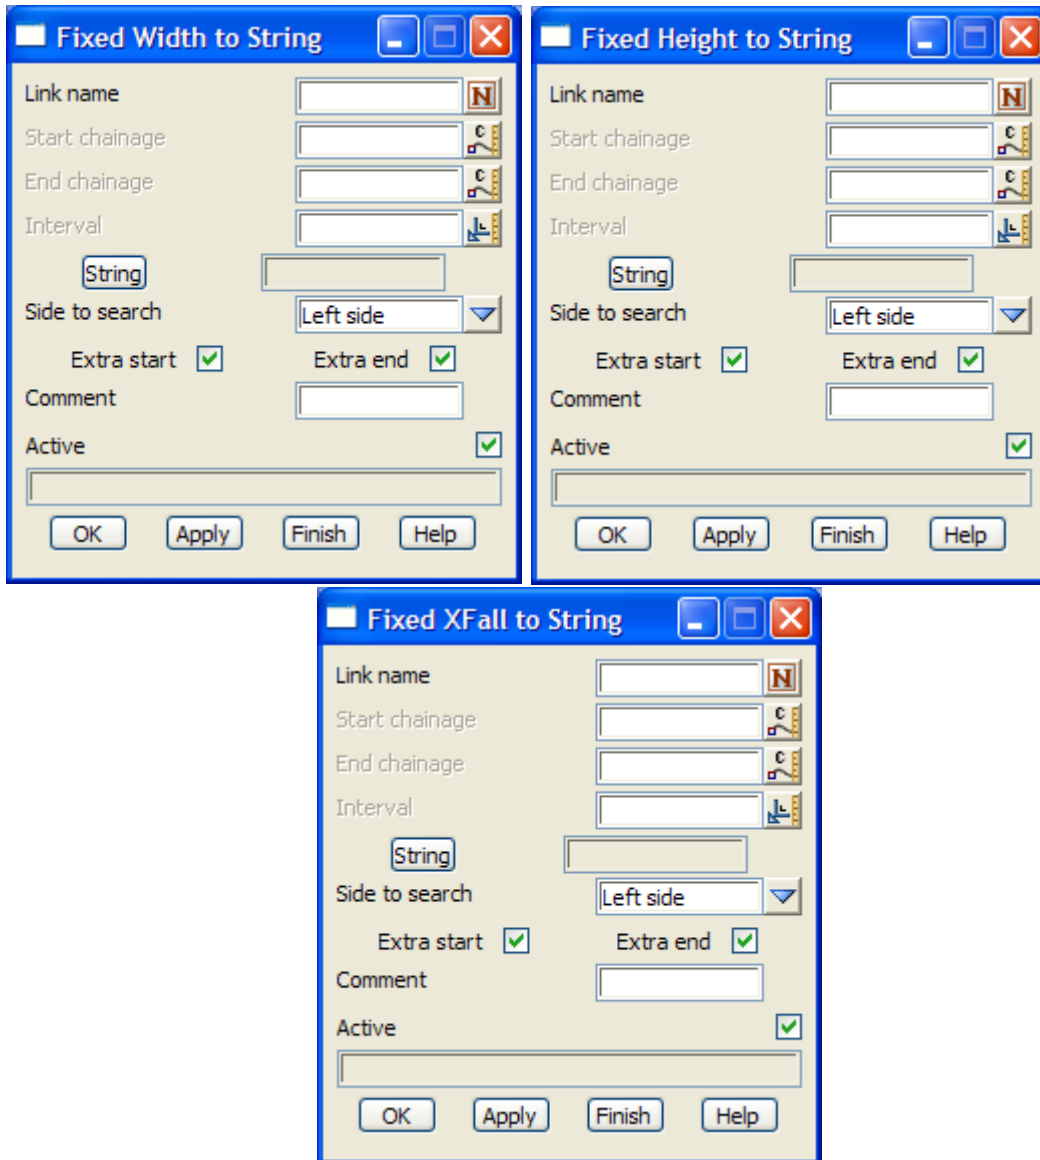

The **width** for a link can be varied by **going out to another 12d Model string**.

The **height** for a link can be varied by **taking the height from another 12d Model string**.

The **xfall** of a link can be defined by using the xfall from the **beginning of the link** (i.e. the end of the previous link or the hinge string if it is the first link) **to another 12d Model string**.

Using two of the above modifiers together and with the same string will place the end point of the link on the selected string. For example, using *width to string* and *xfall to string* with the same string will place the end of the link on that string.

Selecting the width to string, height to string or xfall to string option brings up the **fixed width to string**, **fixed height to string** and **fixed xfall to string** panels respectively.

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Link name <i>name of the link to modify.</i>	input		select name menu
Start/End chainage <i>if non blank, start/end chainages for modifying the template link. If blank, the modifier is applied for the length of the selected string.</i>	input		measures menu
Start/End chainage <i>if non blank, start/end chainages for modifying the template link. If blank, the modifier is applied for the length of the selected string.</i>	input		measures menu
Interval <i>if non blank, the interval to use to create cross sections and strings over the given chainage range. If blank, the Section separation value from the Apply Many panel is used.</i>	input		
String	string-select		

select string to use for defining width/height/crossfall for the link.

Side to search input left side left side, right side, both sides
side of the hinge string to start searching to find the string to define width/height/crossfall.

Extra start/end tick box
if tick, add an extra x-section 0.1 mm before the start/end chainage.

Comment input
comment to add to the end of the line. In the file, the comment will be preceded by //.

Active tick box tick
*if tick, use this modifier.
 if not tick, don't use this modifier.*

OK/Apply button
*OK stores the values in the fields and removes the panel.
 Apply stores the values and leaves the panel on the screen.*

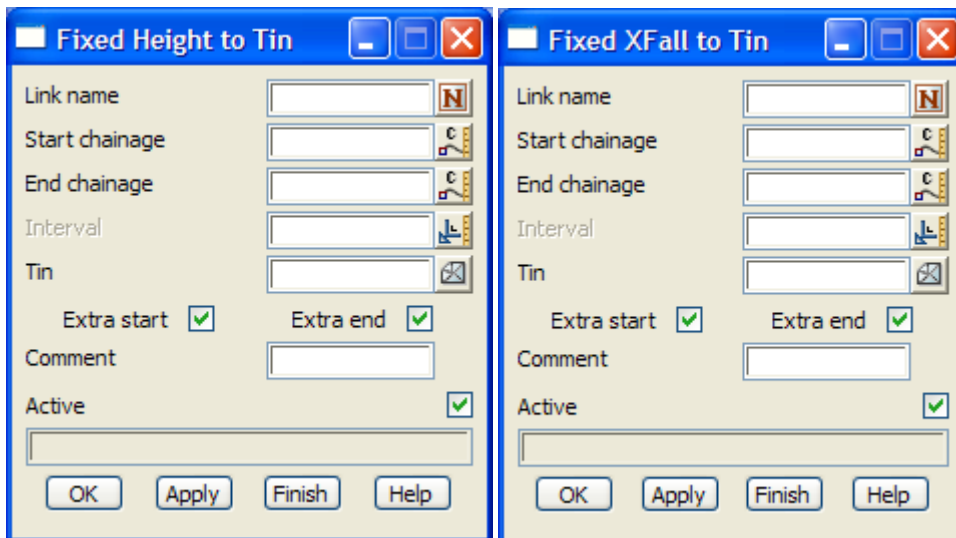

[mtf_edit_modify_fixed_height_to_tin](#) [mtf_edit_modify_fixed_xfall_to_tin](#)

Fixed Height to Tin and Xfall to Tin

The **height to tin** modifier is used to modify the *height* of the link so that the link will sit on the tin at the given width. Note that **height to tin** can only be used for a fixed link defined by *width* and *height*.

The **xfall to tin** modifier is used to modify the *xfall* of the link so that the link will sit on the tin at the given width. Note that **xfall to tin** can only be used for a fixed link defined by *width* and *xfall*.

Selecting the height to tin or xfall to tin option brings up the **fixed height to tin** and **fixed xfall to tin** panels respectively.

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Link name <i>name of the link to modify.</i>	input		select name menu
Start/End chainage	input		measures menu

start/end chainages for modifying the template link.

Interval input

*if **non blank**, the interval to use to create cross sections and strings over the given chainage range.
If **blank**, the Section separation value from the **Apply Many** panel is used.*

Tin input available tins

the tin to use for defining the height/xfall

Extra start/end tick box

*if **tick**, add an extra x-section 0.1 mm **before** the start/end chainage.*

Comment input

comment to add to the end of the line. In the file, the comment will be preceded by //.

Active tick box tick

*if **tick**, use this modifier.
if **not tick**, don't use this modifier.*

OK/Apply button

***OK** stores the values in the fields and removes the panel.
Apply stores the values and leaves the panel on the screen.*

[mtf_edit_modify_fixed_width_to_2_strings](#) [mtf_edit_modify_fixed_height_to_2_strings](#)
[mtf_edit_modify_fixed_xfall_to_2_strings](#)

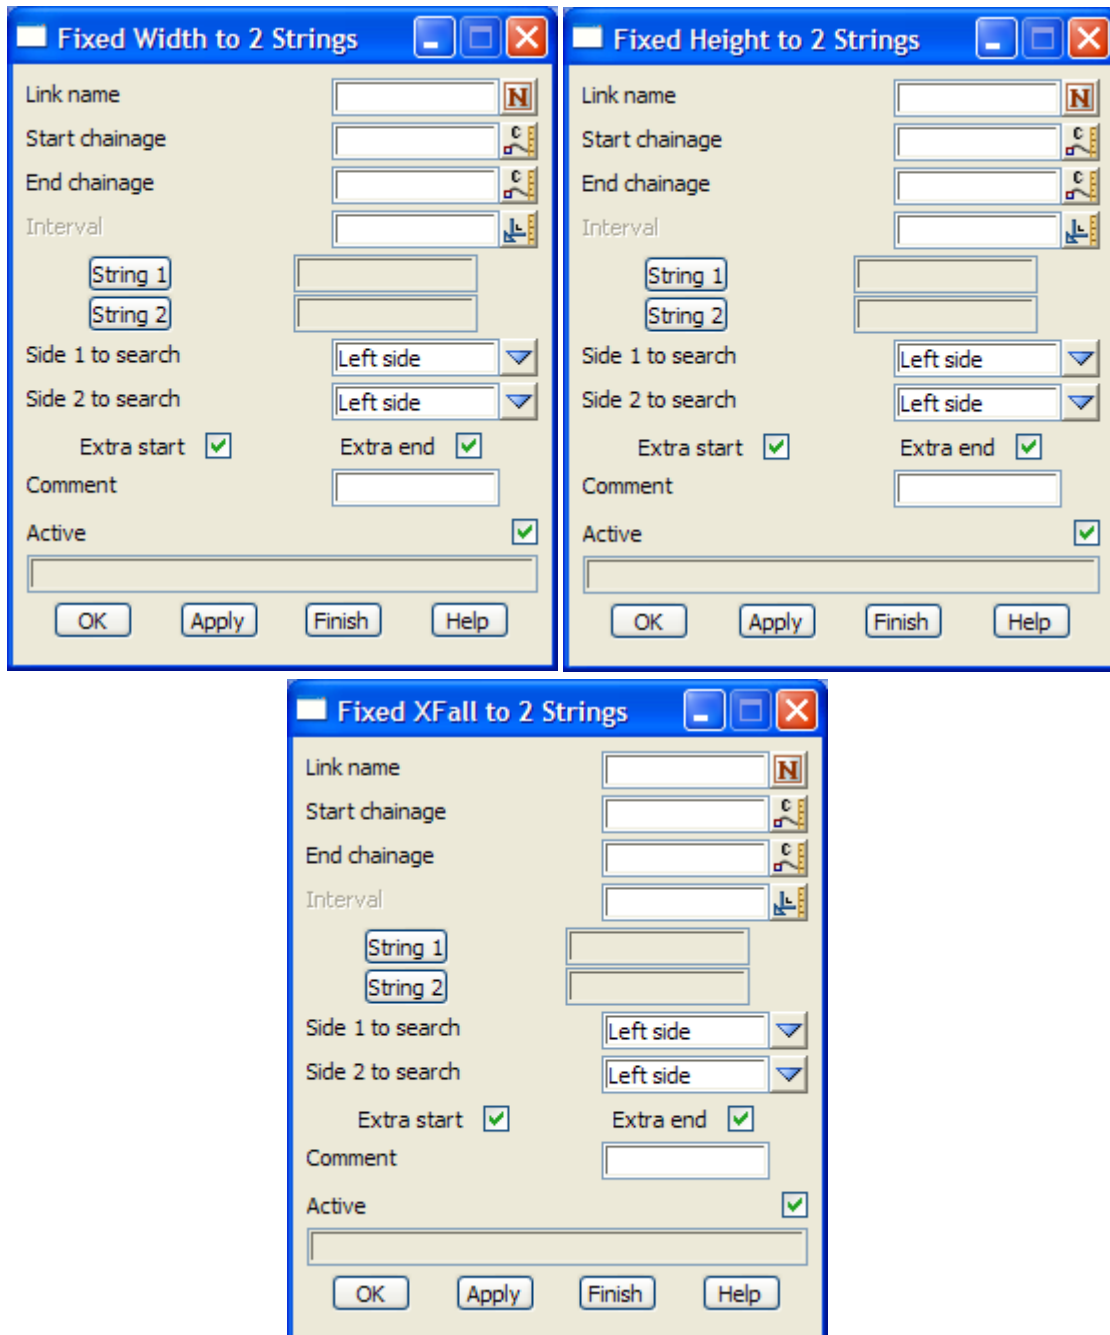

Fixed Width, Height and Xfall between Two Strings

The **width** for a link can be defined by taking the **width between two** existing **12d Model strings**.

The **height** for a link can be defined by taking the **height between two** existing **12d Model strings**.

The **xfall** for a link can be defined by taking the **xfall between two** existing **12d Model strings**.

Selecting the **width to 2 strings**, **height to 2 strings** or **xfall to 2 strings** option brings up the **fixed width to 2 strings**, **fixed height to 2 strings**, and **fixed xfall to 2 strings** panels respectively.

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Link name <i>name of the link to modify.</i>	input		select name menu
Start/End chainage <i>start/end chainages for modifying the template link.</i>	input		measures menu
Interval <i>if non blank, the interval to use to create cross sections and strings over the given chainage range. If blank, the Section separation value from the Apply Many panel is used.</i>	input		
String 1	string-select		

select the first string to use for defining width/height/crossfall for the link.

String 2 string-select

select the second string to use for defining width/height/crossfall for the link.

Side 1 to search input left side left side, right side, both sides

side of the hinge string to start searching to find string 1 to use in defining width/height/crossfall.

Side 2 to search input left side left side, right side, both sides

side of the hinge string to start searching to find string 2 to use in defining width/height/crossfall.

Extra start/end tick box

*if **tick**, add an extra x-section 0.1 mm **before** the start/end chainage.*

Comment input

comment to add to the end of the line. In the file, the comment will be preceded by //.

Active tick box tick

*if **tick**, use this modifier.*

*if **not tick**, don't use this modifier.*

OK/Apply button

***OK** stores the values in the fields and removes the panel.*

***Apply** stores the values and leaves the panel on the screen.*

Please continue to the next section "Decision" .

Decision

[mtf_edit_modify_create_decision](#)

[mtf_edit_decision_change](#)

Decision Change

Each template is made up of the sections fixed, decisions, cut, fill and final cut/fill. If a template has a decisions section then by default the decisions section it is used instead of the cut, fill and final cut/fill sections.

Hence by default, if the decisions section of a template exists then it is used but if the decisions section does not exist, then the cut, fill and final cut/fill sections of the template are used over the chainage range.

For an Apply Many, the template specified for a chainage range in the Templates section of the MTF (see “Templates”) is called the *original* template for that chainage range.

Using the **decision** modifier, it is possible to **override** the defaults for the original template, and for a given chainage range:

use the *decisions* section **from another** template instead of the decisions or cut/fill sections of the original template.

or

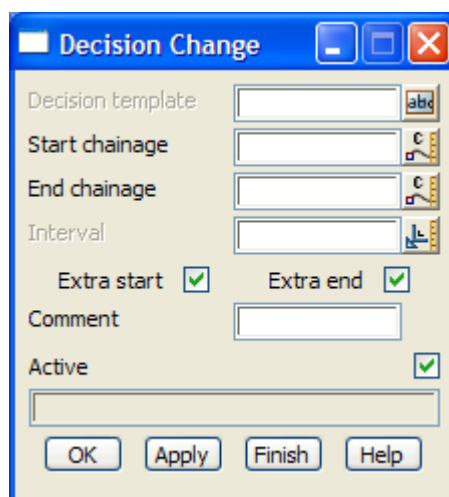

use the cut, fill and final cut/fill sections of the original template **instead** of the decisions section of the original template.

The fixed part of the *original* template is *still used* in either case.

The decision walk-right brings up the decision menu with the change option which nominates what decision templates are used for what chainage ranges.

Selecting the change option brings up the **Decision Change** panel

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Decision template	input		available templates

if **non-blank**, this is the template whose decisions section is used over the given chainage range.
If **blank**, the cut, fill and final cut/fill sections of the original template are used over the chainage range instead of the decision section of the original template.

Note that if the new template has no decisions, then the **cut and fill section** of the original template is used instead of the decisions section of the original template. That is, it is equivalent to leaving the **Decisions template** field blank.

Start/End chainage input measures menu
start/end chainages for using the decisions.

Interval input
*if non blank, the interval to use to create cross sections and vertices of the strings over the given chainage range.
If blank, the Section separation value from the **Apply Many** panel is used.*

Extra start/end tick box
*if tick, add an extra x-section 0.1 mm **before** the start/end chainage.*

Comment input

Apply stores the values and leaves the panel on the screen.*

Please continue to the next section "Cut Modifiers" .

Cut Modifiers

[mtf_edit_modify_create_cut](#)

The Cut walk-right brings up the Cut menu with options to modify the cut links of the template.

For <i>Insert</i> ,	go to the section	"Cut Insert"
<i>Remove</i>		"Cut Remove"
<i>Width/Height</i>		"Cut Width and Height"
<i>Slope</i>		"Cut Slope"
<i>Width/Height/Slope from link</i>		"Cut Width, Height and Slope from a Link"
<i>Width/Height/Slope to string</i>		"Cut Width, Height and Slope to a String"
<i>Height/Slope to tin</i>		"Cut Height to Tin and Slope to Tin"
<i>Width/Height/Slope to 2 strings</i>		"Cut Width, Height and Slope between Two Strings"

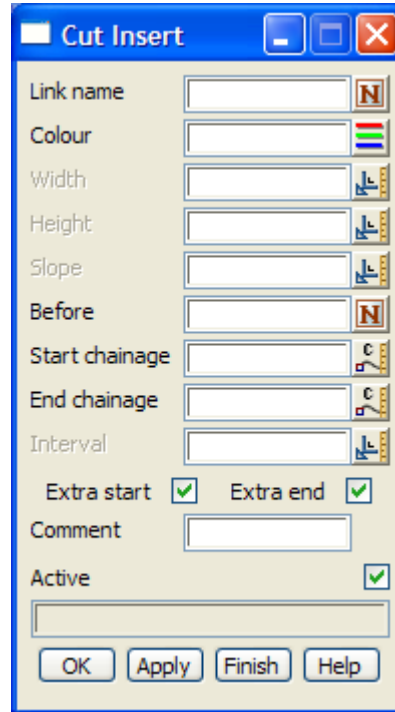

Each of the options from this menu will now be described.

[mtf_edit_modify_cut_insert](#)

Cut Insert

Cut links can be created by the **cut insert** modifier and by specifying either the width and height, width and slope or height and slope.

Selecting the insert option brings up the **Cut Insert** panel

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Link name <i>name of the link to create.</i>	input		select name menu
Colour <i>colour of the link being created.</i>	input		available colours
Width /height/slope <i>width/ height/slope of the link being created - only use two of the three.</i>	input		measures menu
Before <i>if non-blank, the name of the string to insert the new string before. If blank, the link is appended to the end of the fixed part of the template.</i>	input		select name menu
Start/End chainage <i>start/end chainages for inserting the new template link.</i>	input		measures menu
Interval <i>if non blank, the interval to use to create cross sections and vertices of the strings over the given chainage range. If blank, the Section separation value from the Apply Many panel is used.</i>	input		
Extra start/end <i>if tick, add an extra x-section 0.1 mm before the start/end chainage.</i>	tick box		
Comment <i>comment to add to the end of the line. In the file, the comment will be preceded by //.</i>	input		
Active <i>if tick, use this modifier. if not tick, don't use this modifier.</i>	tick box	tick	

OK/Apply button

OK stores the values in the fields and removes the panel.

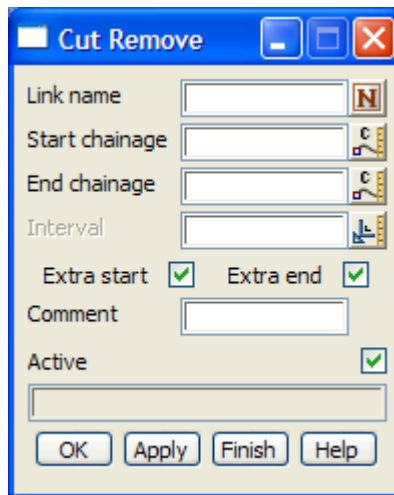

Apply stores the values and leaves the panel on the screen.

`mtf_edit_modify_cut_remove`

Cut Remove

Cut links can be deleted between given chainages by using the **cut remove** modifier.

Selecting the remove option brings up the **cut remove** panel

The fields and buttons used in this panel have the following functions.

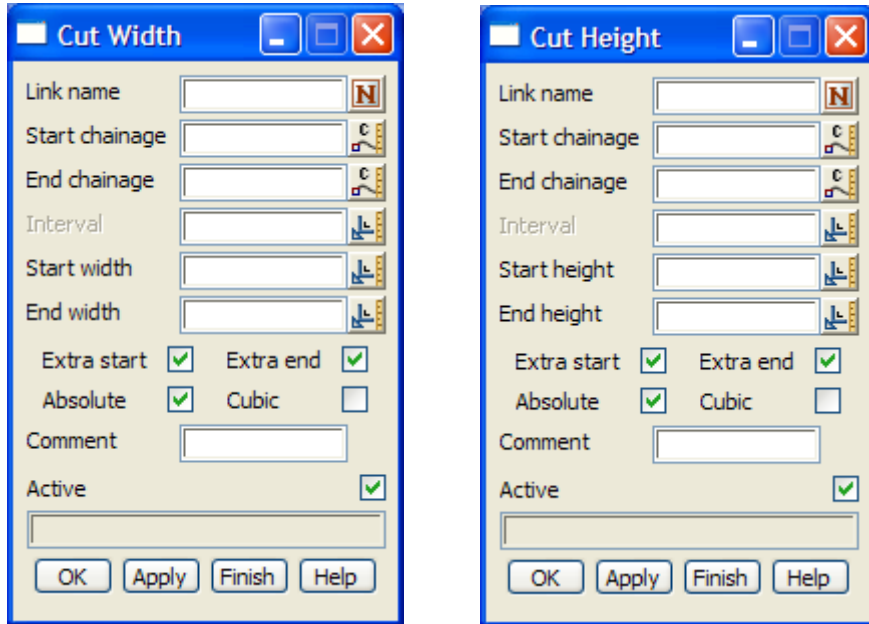

Field Description	Type	Defaults	Pop-Up
Link name <i>name of the link to removed.</i>	input		select name menu
Start/End chainage <i>start/end chainages for removing the template link.</i>	input		measures menu
Interval <i>if non blank, the interval to use to create cross sections and strings over the given chainage range. If blank, the Section separation value from the Apply Many panel is used.</i>	input		
Extra start/end <i>if tick, add an extra x-section 0.1 mm before the start/end chainage.</i>	tick box		
Comment <i>comment to add to the end of the line. In the file, the comment will be preceded by //.</i>	input		
Active <i>if tick, use this modifier. if not tick, don't use this modifier.</i>	tick box	tick	
OK/Apply OK stores the values in the fields and removes the panel. Apply stores the values and leaves the panel on the screen.	button		

`mtf_edit_modify_cut_width` `mtf_edit_modify_cut_height`

Cut Width and Height

The **cut width** modifier is used to modify the width of variable cut links originally defined by width. Similarly the **cut height** modifier is used to modify the height of variable cut links originally defined by height.

Selecting the **width** and **height** option brings up the **cut width** and **cut height** panels respectively.

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Link name <i>name of the link to modify.</i>	input		select name menu
Start/End chainage <i>start/end chainages for modifying the template link.</i>	input		measures menu
Interval <i>if non blank, the interval to use to create cross sections and strings over the given chainage range. If blank, the Section separation value from the Apply Many panel is used.</i>	input		
Start/End width/height <i>start/end width/height for modifying the template link.</i>	input		measures menu
Extra start/end <i>if tick, add an extra x-section 0.1 mm before the start/end chainage.</i>	tick box		
Absolute <i>if tick, the width/height is set to the values given in the start and end value fields. if not tick, the values given in the start and end value fields are added to the existing widths/heights.</i>	tick box	tick	
Cubic <i>if tick, the width/height is varied as a reverse cubic between the start and end chainages. if not tick, the width/height is varied linearly between the start and end chainages.</i>	tick box		
Comment <i>comment to add to the end of the line. In the file, the comment will be preceded by //.</i>	input		

Active tick box tick

*if tick, use this modifier.
if not tick, don't use this modifier.*

OK/Apply button

OK stores the values in the fields and removes the panel.
Apply stores the values and leaves the panel on the screen.

mtf_edit_modify_cut_slope

Cut Slope

The **cut slope** modifier is used to modify the slope of variable cut links originally defined by slope.

Selecting the slope option brings up the **cut slope** panel

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Link name <i>name of the link to modify.</i>	input		select name menu
Start/End chainage <i>start/end chainages for modifying the template link.</i>	input		measures menu
Interval <i>if non blank, the interval to use to create cross sections and strings over the given chainage range. if blank, the Section separation value from the Apply Many panel is used.</i>	input		
Start/End slope <i>start/end slope for modifying the template link.</i>	input		measures menu
Extra start/end <i>if tick, add an extra x-section 0.1 mm before the start/end chainage.</i>	tick box		

Absolute tick box tick

if tick, the slope is set to the values given in the start and end slope fields.

if not tick, the slopes given in the start and end value fields are added to the existing slopes.

Cubic and Rotate tick boxes:

Only none or one of Cubic and Rotate can be set to tick.

The default is none - that is, neither is ticked and in the default case, the slope is varied linearly with respect to slope between the start and end chainages.

Cubic tick box

if tick, the slope is varied as a reverse cubic between the start and end chainages.

Rotate tick box

if tick, the slope is varied linearly with respect to the angle, between the start and end chainages.

Comment input

comment to add to the end of the line. In the file, the comment will be preceded by //.

Active tick box tick

if tick, use this modifier.

if not tick, don't use this modifier.

OK/Apply button

OK stores the values in the fields and removes the panel.

Apply stores the values and leaves the panel on the screen.

[mtf_edit_modify_cut_width_from_link](#) [mtf_edit_modify_cut_height_from_link](#)
[mtf_edit_modify_cut_slope_from_link](#)

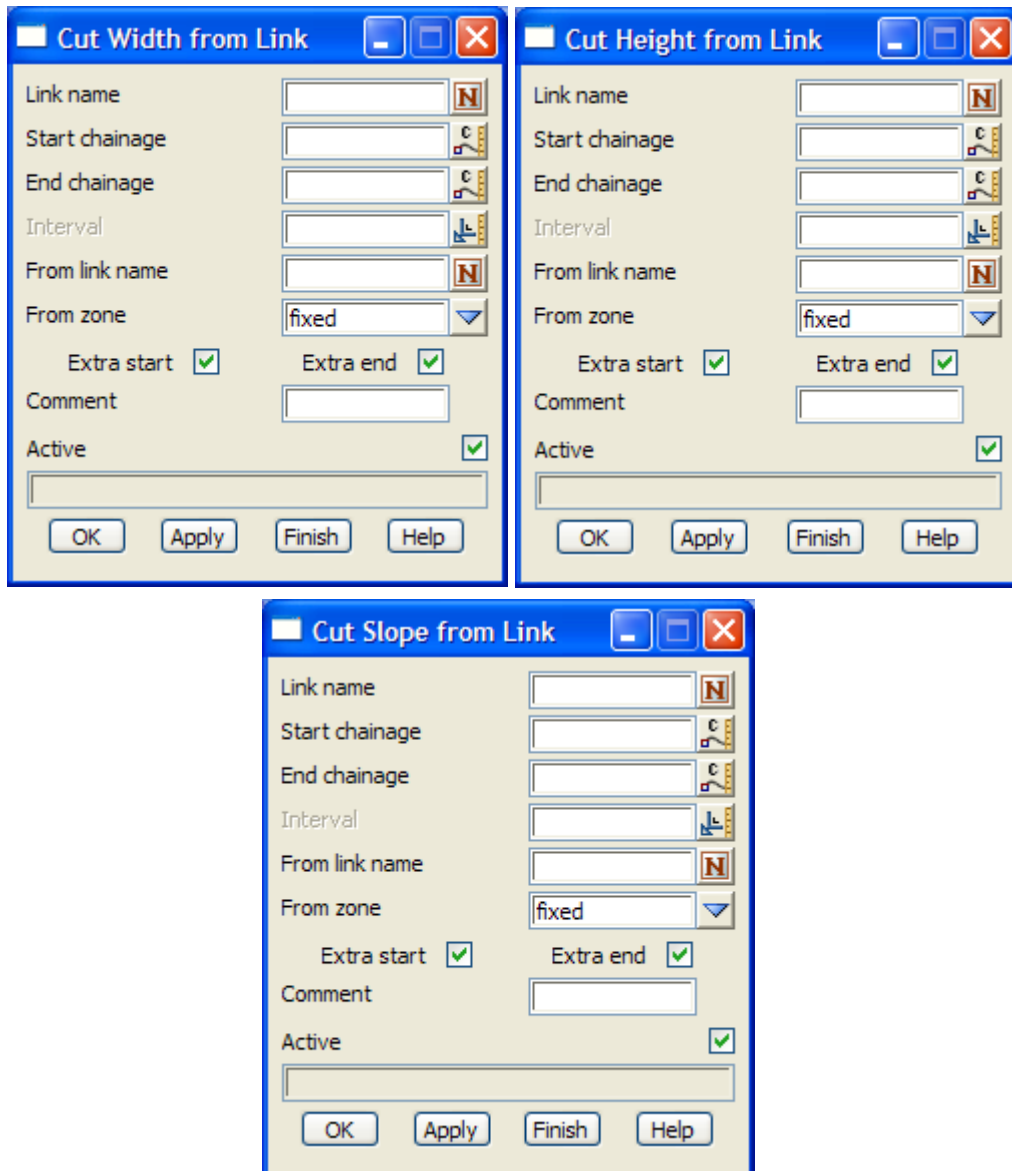

Cut Width, Height and Slope from a Link

The **width from link** modifier is used to modify the width of cut links originally defined by width to be the same width as another link. That is, the width of the link is a copy of the width of another link.

The **height from link** modifier is used to modify the height of cut links originally defined by height to be the same height as another link. That is, the height of the link is a copy of the height of another link.

The **slope from link** modifier is used to modify the slope of cut links originally defined by slope to be the same slope as another link. That is, the slope of the link is a copy of the slope of another link. The link to copy slope from can be defined in terms of slope or cross fall. If the link to copy is defined by cross fall, then the slope is calculated to match the cross fall.

Selecting the width from link, height from link or slope from link option brings up the **cut width from link**, **cut height from link** and **cut slope from link** panels respectively.

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Link name <i>name of the link to modify.</i>	input		select name menu
Start/End chainage <i>start/end chainages for modifying the template link.</i>	input		measures menu
Interval <i>if non blank, the interval to use to create cross sections and strings over the given chainage range. If blank, the Section separation value from the Apply Many panel is used.</i>	input		
From link name <i>template link to take width/height/slope from.</i>	input		select name menu
From zone <i>zone that the template link to take width/height/slope from, comes from.</i>	input	fixed	fixed, cut, fill

Extra start/end tick box

*if **tick**, add an extra x-section 0.1 mm **before** the start/end chainage.*

Comment input

comment to add to the end of the line. In the file, the comment will be preceded by //.

Active tick box tick

*if **tick**, use this modifier.*

*if **not tick**, don't use this modifier.*

Fill Width, Height and Slope to a String

The **width** for a fill link can be varied by **going out to another** existing **string**.

The **height** for a fill link can be varied by **taking the height from another** existing **string**.

The **slope** of a fill link can be defined by using the slope from the **beginning of the link** (i.e. the end of the previous link or the hinge string if it is the first link) **to another** existing **string**.

Selecting the width to string, height to string or slope to string option brings up the fill width to string, fill height to string and fill slope to string panels respectively.

The fields and buttons used in this panel have the following functions.

Field	Description	Type	Defaults	Pop-Up
Link name	<i>name of the link to modify.</i>	input		select name menu
Start/End chainage	<i>if non blank, start/end chainages for modifying the template link. If blank, the modifier is applied for the length of the selected string.</i>	input		measures menu
Interval	<i>if non blank, the interval to use to create cross sections and strings over the given chainage range. If blank, the Section separation value from the Apply Many panel is used.</i>	input		
String	<i>select string to use for defining width/height/slope for the link.</i>	string-select		
Side to search		input	left side	left side, right side, both sides

side of the hinge string to start searching to find the string to define width/height/slope.

Extra start/end tick box

if **tick**, add an extra x-section 0.1 mm **before** the start/end chainage.

Comment input

comment to add to the end of the line. In the file, the comment will be preceded by //.

Active tick box tick

if **tick**, use this modifier.

if **not tick**, don't use this modifier.

OK/Apply button

OK stores the values in the fields and removes the panel.

Apply stores the values and leaves the panel on the screen.

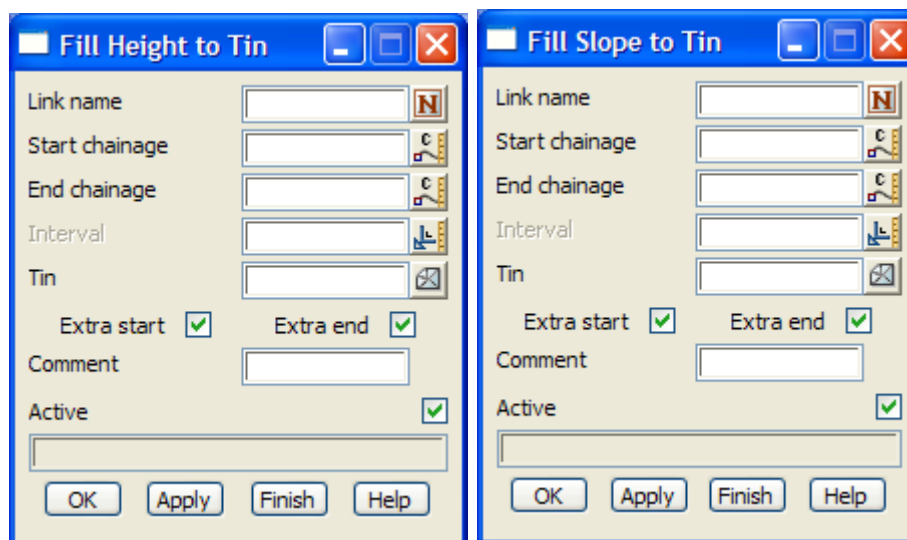

The typed formats of the width to a string, height to a string and slope to a string command for a [mtf_edit_modify_fill_height_to_tin](#) [mtf_edit_modify_fill_slope_to_tin](#)

Fill Height to Tin and Slope to Tin

The **height to tin** modifier is used to modify the height of the fill link so that the link will sit on the tin at the given width. Note that **height to tin** can only be used for a fill link defined by *width* and *height*.

The **slope to tin** modifier is used to modify the slope of the link so that the link will sit on the tin at the given width. Note that **slope to tin** can only be used for a cut link defined by *width* and *slope*.

Selecting the height to tin or slope to tin option brings up the **fill height to tin** and **fill slope to tin** panels respectively.

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Link name	input		select name menu
<i>name of the link to modify.</i>			
Start/End chainage	input		measures menu

start/end chainages for modifying the template link.

Interval input

*if **non blank**, the interval to use to create cross sections and strings over the given chainage range.
If **blank**, the Section separation value from the **Apply Many** panel is used.*

Tin input available tins

the tin to use for defining the height/slope

Extra start/end tick box

*if **tick**, add an extra x-section 0.1 mm **before** the start/end chainage.*

Comment input

comment to add to the end of the line. In the file, the comment will be preceded by //.

Active tick box tick

*if **tick**, use this modifier.*

*if **not tick**, don't use this modifier.*

OK/Apply button

OK stores the values in the fields and removes the panel.

Apply stores the values and leaves the panel on the screen.

[mtf_edit_modify_fill_slope_to_2_strings](#)

Fill Width, Height and Slope between Two Strings

The **width** for a fill link can be defined by taking the **width between two existing strings**.

The **height** for a fill link can be defined by taking the **height between two existing strings**.

The **slope** for a fill link can be defined by taking the **slope between two existing strings**.

Selecting the width to 2 strings, height to 2 strings or slope to 2 strings option brings up the **fill width to 2 strings**, **fill height to 2 strings** and **fill slope to 2 string** panels respectively.

The image shows three dialog boxes for template modification:

- Fill Width to 2 Strings:** Contains fields for Link name, Start chainage, End chainage, Interval, String 1, String 2, Side 1 to search (Left side), Side 2 to search (Left side), Extra start (checked), Extra end (checked), Comment, and Active (checked). Buttons: OK, Apply, Finish, Help.
- Fill Height to 2 Strings:** Identical layout to the Width dialog.
- Fill Slope to 2 Strings:** Identical layout to the Width dialog.

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Link name <i>name of the link to modify.</i>	input		select name menu
Start/End chainage <i>start/end chainages for modifying the template link.</i>	input		measures menu

mtf_edit_modify_final_cut_slope mtf_edit_modify_final_fill_slope

Final Cut or Final Fill Slope

The final **cut slope** modifier varies the cut slope of the *final* link of the template and the final **fill slope** modifier varies the fill slope of the *final* link of the template.

Selecting the cut slope or fill slope options brings up the **cut slope** and **fill slope** panels respectively.

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Link name	input		select name menu

name of the link to modify.

Start/End chainage	input		measures menu
---------------------------	-------	--	---------------

start/end chainages for modifying the template link.

Interval	input		
-----------------	-------	--	--

*if non blank, the interval to use to create cross sections and strings over the given chainage range.
If blank, the Section separation value from the Apply Many panel is used.*

Start/End slope	input		measures menu
------------------------	-------	--	---------------

start/end slope for modifying the template link.

Extra start/end	tick box		
------------------------	----------	--	--

if tick, add an extra x-section 0.1 mm before the start/end chainage.

Absolute	tick box	tick	
-----------------	----------	------	--

*if tick, the slope is set to the values given in the start and end slope fields.
if not tick, the values given in the start and end slope fields are added to the existing slope.*

Cubic	tick box		
--------------	----------	--	--

if tick, the slope is varied as a reverse cubic between the start and end chainages.

Rotate	tick box		
---------------	----------	--	--

if tick, the slope is varied linearly with respect to the angle, between the start and end chainages.

Note -

Only one of cubic and rotate can be set to tick.

If both are set to not tick, then the slope is varied linearly respect to slope between the start and end chainages (the default).

Comment	input		
----------------	-------	--	--

comment to add to the end of the line. In the file, the comment will be preceded by //.

Active tick box tick

*if tick, use this modifier.
if not tick, don't use this modifier.*

OK/Apply button

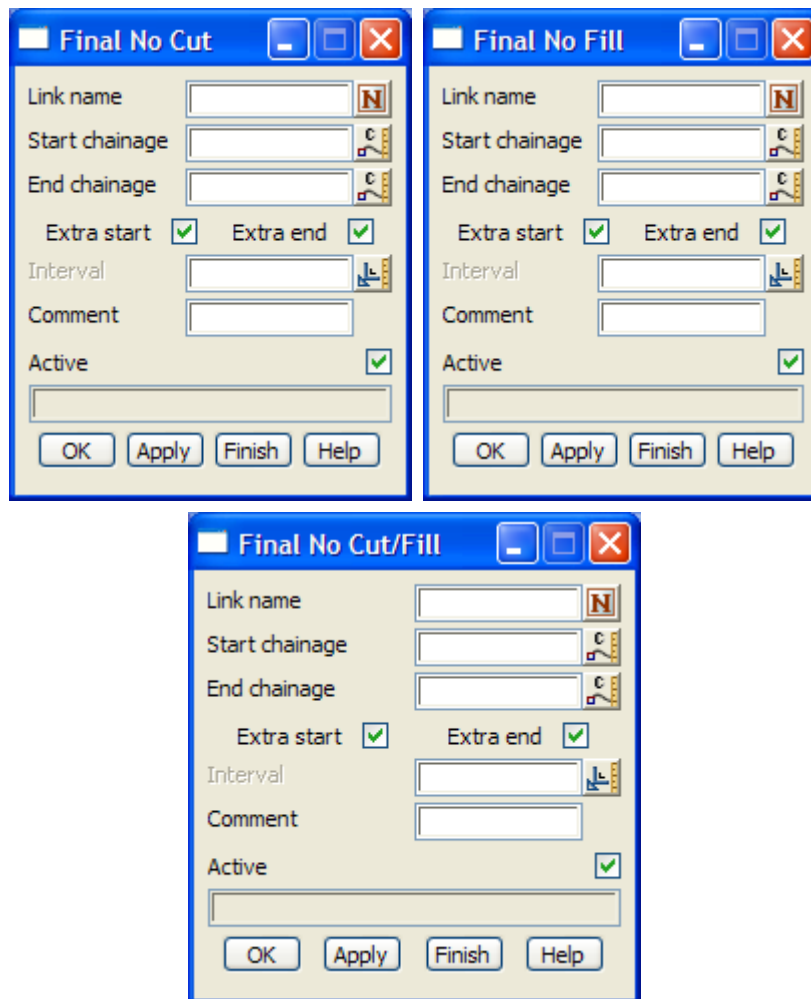

*OK stores the values in the fields and removes the panel.
Apply stores the values and leaves the panel on the screen.*

- mtf_edit_modify_final_no_cut
- mtf_edit_modify_final_no_fill
- mtf_edit_modify_final_no_cut_fill

Final No Cut Slope and/or Final No Fill Slope

The final link can be stopped altogether in either cut or fill or both. The **no cut slope** modifier stops the final link when it is in *cut*, the **no fill slope** modifier stops the final link when it is in *fill* and the **no cut/fill fill slope** modifier stops the final link when it is in *cut and fill*.

Selecting the No cut slope, No fill slope or No cut/fill slope options brings up the **Final No Cut**, **Final No Fill** or **Final No Cut/Fill** panels or respectively.

The fields and buttons used in this panel have the following functions.

Field	Description	Type	Defaults	Pop-Up
-------	-------------	------	----------	--------

Link name	input	select name menu
	<i>name of the link to modify.</i>

	<i>OK stores the values in the fields and removes the panel.</i>	
	<i>Apply stores the values and leaves the panel on the screen.</i>	

Please continue to the next section "Stripping" .

Stripping

mtf_edit_stripping_changes

A fixed stripping depth can be specified in the apply option whilst the **apply many** option allows for stripping depths which can **vary along the design**.

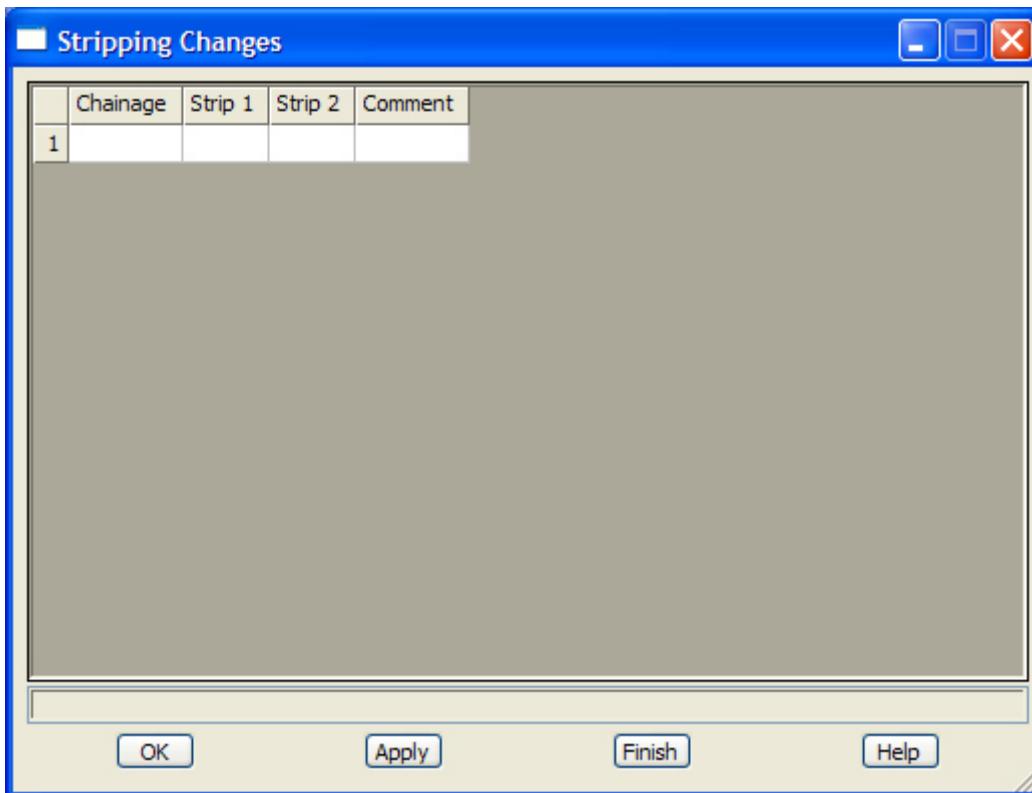

If a non-zero stripping depth exists at a chainage, the **cut** and **fill** calculations are done with respect to the section through the tin dropped in height by the stripping depth.

However, the **design strings** are generated by battering into the **unstripped** surface, and the stripping volume is the volume between the stripped and unstripped surface for the design.

Stripping depths are defined for chainages along the reference string and can be linearly interpolated between chainages.

NOTE: Cut and fill areas and volumes are adjusted for the stripping depths. The total stripping volume is given at the end of the volumes report.

Selecting the stripping option on the MTF edit menu brings up the **stripping changes** panel

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Chainage	column header		
<i>list of chainages for defining stripping depth.</i>			
Strip depth 1	column header		for the field - measures menu
<i>strip depth to apply at the chainage given for this row of information. If strip depth 2 is blank, then strip depth 1 is applied until the next chainage in the chainage column.</i>			

Strip depth 2 column header for the field - measures
menu

if non-blank, the strip depth to linearly interpolate to and finish with at the next chainage in the chainage column.

if blank, then strip depth 1 applies to the next chainage in the chainage column.

In the mtf file, the two depths will be separated by a comma.

Comment column header

comment to add to the end of the line. In the file, the comment will be preceded by //.

OK/Apply button

OK stores the values in the fields and removes the panel.

Apply stores the values and leaves the panel on the screen.

Please continue to the next section "Boxing" .

Boxing

mtf_edit_boxing

In the **many templates file**, up to eight (8) layers of boxing can be defined.

For each layer, the boxing is defined in one or two parts - the left boxing and the right boxing.

The left boxing or the right boxing can define the boxing for the entire template and then only one is needed.

If left and right boxing are **both** defined at a section, then the *last point of the left boxing* is automatically connected to the *first point of the right boxing*.

Warning - the left boxing must end before the right boxing begins. If there is an overlap, the right boxing will be pushed to the end of the left boxing.

Warning - no interpolation or modifiers exist for boxing.

For the definition of boxing, go to the section “Full Definition of Boxing”

When boxing is used in the **Apply many**, the cut and fill areas and volumes are also calculated for all the inter-boxing layers. The **last layer** defined is also referred to as the **subgrade** layer and volumes are also given for the natural surface to the subgrade and the design to the subgrade.

The boxing walk-right in the mtf edit menu brings up the boxing menu with options to specify the file supplying the boxing definitions and options to apply the definitions to the right and left side of the template.

For	<i>File</i> ,	go to the section	“Boxing File”
	<i>Left/Right side</i>		“Left Side and Right Side Boxing”
	<i>Left/Right side for each layer</i>		“Left Side and Right Side Boxing”

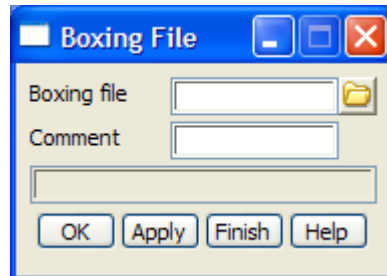

Each of the options from this menu will now described.

mtf_edit_boxing_file

Boxing File

Selecting file from the boxing menu brings up the **boxing file** panel for defining the boxing definitions to be used in this apply many.

For the definition of boxing, go to the section “Full Definition of Boxing”

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Boxing file <i>name of the file containing the boxing definitions to be used for the mtf.</i>	input		*.bf files
Comment <i>comment to add to the end of the line. In the file, the comment will be preceded by //.</i>	column header		
OK/Apply <i>OK stores the values in the fields and removes the panel. Apply stores the values and leaves the panel on the screen.</i>	button		

[mtf_edit_boxing_changes](#)

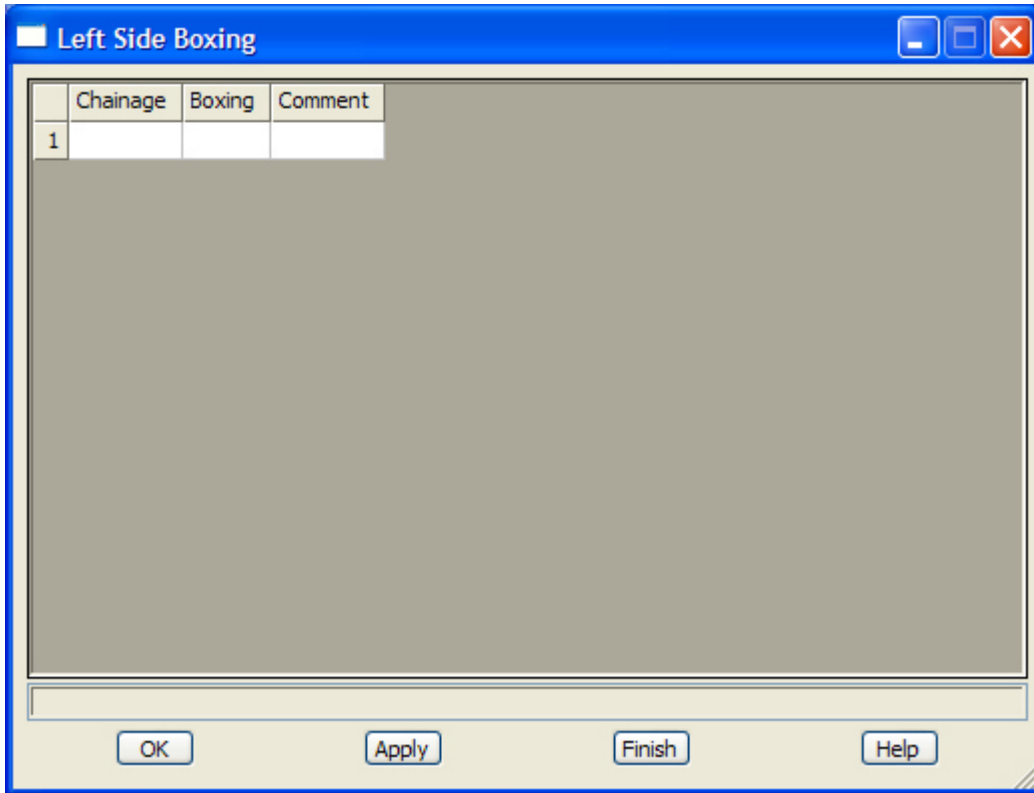

Left Side and Right Side Boxing

The panels brought up by selecting Left side or Right side from the Boxing menu brings up the **Left Side Boxing** and **Right Side Boxing** panels respectively. This is for the first layer of boxing.

The left side and right side panels define for each boxing layer, what boxing definitions (from the boxing file) are applied to chainages along the reference string.

For the definition of boxing, go to the section “Full Definition of Boxing”

The panels brought up by selecting Left side or Right side for Layer 2 to Layer 8 from the Boxing menu brings up similar panels for each of the layers and so won't be documented separately.

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
-------------------	------	----------	--------

Chainage column header
chainage to start applying the boxing definition at.

Boxing rule column header for the fields - available boxing
boxing definition to apply from this chainage to the next in the chainage list.

Comment column header
comment to add to the end of the line. In the file, the comment will be preceded by //.

OK/Apply button
OK stores the values in the fields and removes the panel.
Apply stores the values and leaves the panel on the screen.

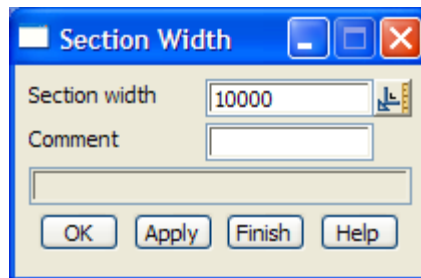

Please continue to the next section "Width" .

Width

mtf_edit_section_width

A **section width** is used to limit the distance to search along a section when trying to find strings used in any of the mtf commands.

Selecting width from the mtf edit men brings up the **section width** panel for setting the width.

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Section width	input	10000	

***Section width** defines the perpendicular offset from the Hinge string. It is used to limit the search distance for strings when performing MTF modifier commands.*

Comment column header

comment to add to the end of the line. In the file, the comment will be preceded by //.

OK/Apply button

***OK** stores the values in the fields and removes the panel.*

***Apply** stores the values and leaves the panel on the screen.*

Please continue to the next section “String Modifiers” .

String Modifiers

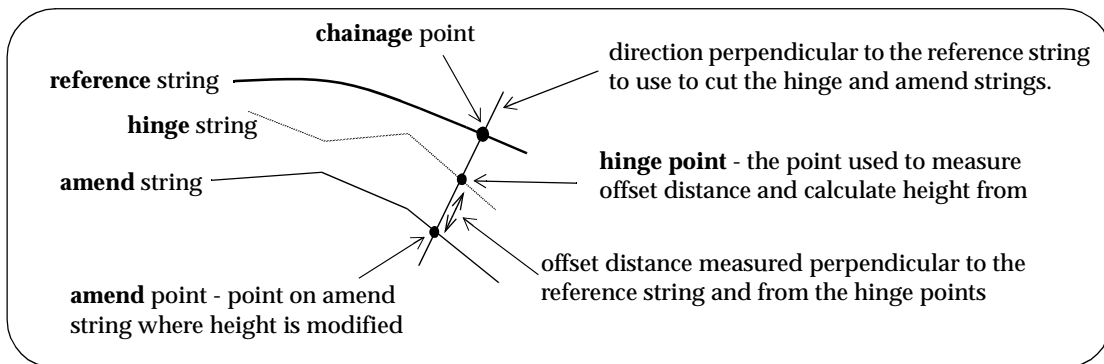

Unlike the other MTF options, the **string modifier** options modify the *heights* on an **existing** string called the **amend string**.

Like the apply options, a reference string is used to define chainage and what is perpendicular at each chainage. A hinge string is used to define offsets and heights. If no hinge string is selected, the reference string is also used as the hinge string.

For a given chainage on the reference string (chainage point), a line perpendicular to the reference string is constructed to cut through the hinge string and the amend string (the cut points are called the **hinge point** and the **amend point**).

Horizontal offset is defined as the offset value from the hinge point, and the height of the **amend** point is a modification of the height at the hinge point.

The string modifier options create and/or modify the heights of the **amend** points on the amend string.

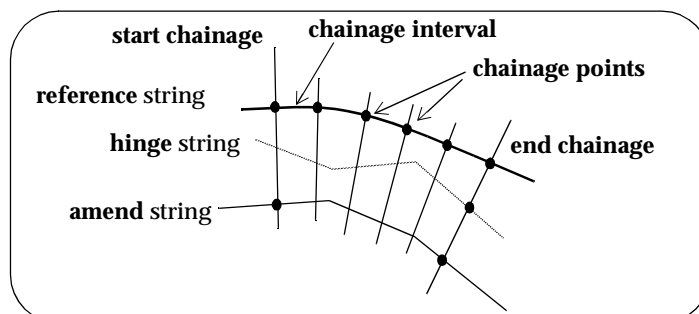

The *height* of the amend point is *derived from the hinge point* by starting with the height of the hinge point and applying a crossfall to it across the offset distance from the hinge string to the amend string.

The cross fall can be defined by either:

- (a) giving the cross fall
- or
- (b) using the cross fall between two user selected strings.

For the string options, the length of string being modified is restricted by giving a start and end reference chainage. A chainage interval can also be specified to define extra reference chainage points to use between the start and end chainages.

How and where the amend string is modified depends on the *type* of string and whether the chainage interval is blank (null) or not.

What Points are Modified

For 3d, 4d, polyline and super strings:

If the chainage interval is not blank:

- (a) The start and end chainage points are projected *from the reference string* and **inserted** into the **amend** string. The *heights* of the inserted points are defined by the string modifier command.
- (b) The chainage points at the given chainage interval are also projected from the reference string and **inserted** into the **amend** string. The *heights* of the inserted points are defined by the string modifier command.
- (c) Finally, the **vertices** of the **amend** string are dropped perpendicularly *back onto* the hinge and reference string and then those points used to modify the *heights* of the same vertices of the amend string.

If the chainage interval is blank:

- (a) The start and end chainage points are projected *from the reference string* and **inserted** into the **amend** string. The *heights* of the inserted points are defined by the string modifier command.
- (b) The **vertices** of the **amend** string are dropped perpendicular *back onto* the hinge and reference string and then those points used to modify the *heights* of the same vertices of the amend string.

For Alignment strings:

If the chainage interval is not blank:

- (a) All the vertical geometry is removed between the start and end chainages. That is, the vertical intersection points (VIP's) and their associated vertical curves are removed.
- (b) The start and end chainage points are projected *from the reference string* and **vertical intersection points (VIP's)** **inserted** into the **amend** string. The *height* of the inserted VIP points are defined by the string modifier command.

If the chainage interval is blank:

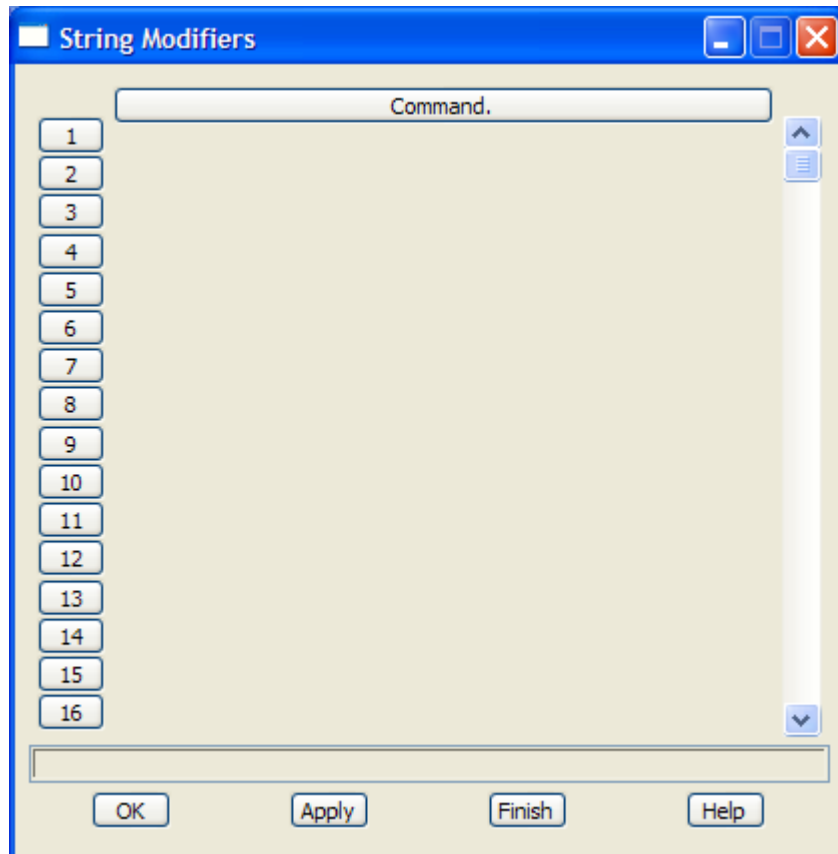

- (a) The start and end chainage points are projected *from the reference string* and **vertical intersection points (VIP's)** **inserted** into the **amend** string. The *heights* of the inserted VIP points are defined by the string modifier command.
- (b) The **vertical intersection points (VIP's)** of the **amend** string are dropped perpendicularly *back onto* the hinge and reference strings and then those points used to modify the *heights* of the same VIP's of the amend string. The vertical curves for the VIP's are not changed.

[string_modifiers](#)

String Modifiers in MTF Edit

For information on how the String Modifiers in the MTF editor work, please go to the previous section “String Modifiers” .

Selecting Strings from the MTF Edit menu brings up the **String Modifiers** panel.

The **String Modifiers** panel consists of a scrolling command fields and an **OK** or **Apply** button to record the results.

The **width** of the command area in the **String Modifiers** panel is controlled by the environment variable `DEFAULT_TABLE_WIDTH_4D`.

[create_mtf_string_modifiers](#)

If the command line is **empty**, clicking LB in the command line will bring up the Create menu which contains the available String commands.

modify by xfall and height
 modify by 2-strings
 comment

Selecting a menu item will bring up an associated panel which displays the information required for the modifier command.

When the panel is filled in and **OK** or **Apply** selected, the panel information is written out to the command line in the correct format for that modifier command.

If the command line is **not empty**, clicking LB in the command line will bring up the associated panel for the modifier command in the command line.

The information in the panel can be changed and if **OK** or **Apply** is selected, the changed panel information is written out to the command line in the correct format for that modifier command.

Each of the panels created by selecting a command from the Create menu, will now be described.

mtf_edit_string_modify_by_xfall_height

Height

The *height* the Height string modifier calculates for the amend point is given by:

- (a) if the absolute flag is not set, the height of the hinge point, otherwise zero.
- plus
- (b) the interpolated height for the user given heights at the start and end chainages
- plus
- (c) the interpolated height for the user given cross falls at the start and end chainage.

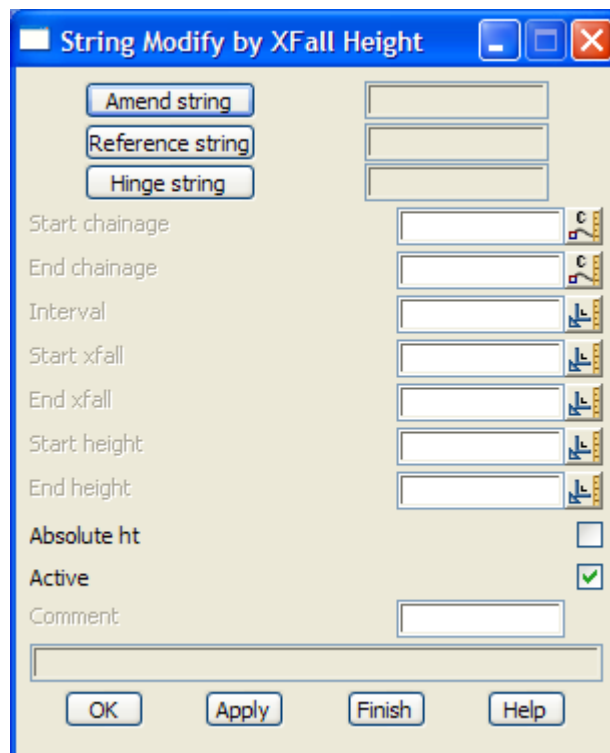

That is, if the absolute flag is not set:

$$\text{new height} = \text{hinge height} + (\text{interpolated height}) + (\text{interpolated xfall}) \times (\text{offset distance})$$

If the absolute flag is set:

$$\text{new height} = (\text{interpolated height}) + (\text{interpolated xfall}) \times (\text{offset distance})$$

Selecting the Height option brings up the **String Modify by Xfall Height** panel

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Amend string <i>select string to have heights amended.</i>	string-select		
Reference string <i>select reference string.</i>	string-select		
Hinge string <i>select hinge string.</i>	string-select		
Start/End chainage <i>start/end chainage on the reference string for applying the modifier.</i>	input		measures menu
Interval <i>if non blank, the chainage separation to apply the modifier. if blank, the Section separation value from the Apply Many panel is used.</i>	input		
Start/End xfall <i>start/end crossfall for the modifier.</i>	input		measures menu
Start/End height <i>start/end height for modifier.</i>	input		measures menu
Absolute height <i>if tick, the calculated height does not include the hinge height. if not tick, the calculated height includes the hinge height.</i>	tick box		
Comment <i>comment to add to the end of the line. In the file, the comment will be preceded by //.</i>	input		
Active <i>if tick, use this modifier. if not tick, don't use this modifier.</i>	tick box	tick	
OK/Apply <i>OK stores the values in the fields and removes the panel. Apply stores the values and leaves the panel on the screen.</i>	button		

For more information on how the String Modifiers in the MTF editor work, please go to the section "String Modifiers" .

[mtf_edit_string_modify_by_2_strings](#)

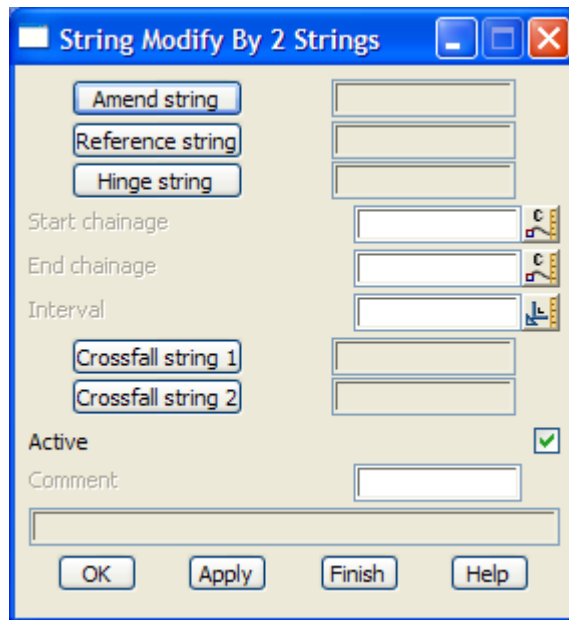

Height 2X

The *height* the Height 2x string modifier calculates for the amend point is given by:

- (a) the height of the hinge point
- plus
- (b) the offset distance multiplied by the cross fall between two user selected strings.

$$\text{new height} = \text{hinge height} + (\text{xfall between string 1 and string 2}) \times (\text{offset distance})$$

Selecting the Height 2x option brings up the **String Modify by 2 Strings** panel

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Amend string <i>select string to have heights amended.</i>	string-select		
Reference string <i>select reference string.</i>	string-select		
Hinge string <i>select hinge string.</i>	string-select		
Start/End chainage <i>start/end chainage on the reference string for applying the modifier.</i>	input		measures menu
Interval <i>if non blank, the chainage separation to apply the modifier. If blank, the Section separation value from the Apply Many panel is used.</i>	input		
Crossfall string 1 <i>select first string to define crossfall by.</i>	string-select		
Crossfall string 2 <i>select second string to define crossfall by.</i>	string-select		
Comment <i>comment to add to the end of the line. In the file, the comment will be preceded by //.</i>	input		
Active <i>if tick, use this modifier. if not tick, don't use this modifier.</i>	tick box	tick	
OK/Apply <i>OK stores the values in the fields and removes the panel.</i>	button		

Apply stores the values and leaves the panel on the screen.

For more information on how the String Modifiers in the MTF editor work, please go to the section “String Modifiers” .

Shift

mtf_edit_shift_chainages

In an *mtf*, many modifiers are defined in terms of chainage on the reference string. For example, the width modifier is defined to apply between a given start and end chainage on the reference string.

If the horizontal geometry of the reference string is modified, many of the reference chainages in the *mtf* will be incorrect. **Shift** can help correct the chainages in the *mtf* file when modifications are made to the reference string horizontal geometry *after the mtf has been defined*.

For the *mtf* and all special chainage files referred to in the *mtf*, **Shift** adds a delta chainage (the *shift distance*) to chainages within a user specified range.

However depending on the type of modifications made to the reference string, **shift** may have to be applied a number of times over a number of different chainage ranges. And apart from a simple change of start chainage, there may be chainages that can not be corrected with **Shift**.

Before using **Shift**, it is necessary to know **how** the reference string has changed from its original position so to use **shift** it is advantageous to make a **copy** of the reference string **before** any changes are made.

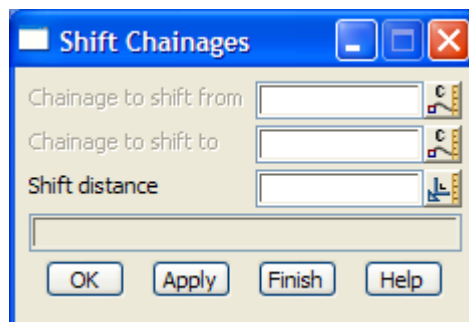

Examples Using Shift:

1. If only the start chainage of the reference string was modified, **shift** would be applied to the *mtf* for the entire **original** reference string and end chainages, with a *shift distance* equal to the difference between the new and the old start chainages for the reference string. For this case the horizontal geometry has not changed, just the chainages.
2. If the radius of a horizontal curve is changed in the middle of the reference string, all chainages from the beginning of the string up to point where the horizontal geometry starts to change would stay the same. At some point after the modified curve, the horizontal geometry of the string is unchanged and for this section of the *mtf*, a shift distance equal to the difference between the new and the old chainages of a non-modified point.

In all areas where the horizontal geometry has been modified, the chainages in the *mtf* would have to be carefully examined to see what changes are required.

Warning: Shift option is very powerful but is also very dangerous.

Selecting **Shift** brings up the **Shift Chainages** panel.

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Chainage to shift from	chainage box		measure chainage
<i>chainage in the mtf to start adding the Shift distance</i>			

*Any chainages in the mtf file (and any associated special chainage files) between the **Chainage to shift from** and the **Chainage to shift to** will have Shift distance added to them.*

Chainage to shift to chainage box measure chainage
chainage in the mtf to stop adding the Shift distance

*Any chainages in the mtf file (and any associated special chainage files) between the **Chainage to shift from** and the **Chainage to shift to** will have Shift distance added to them.*

Shift distance input
*delta chainage to add to all the chainages in the mtf file and any special chainages that are between the **Chainage to shift from** and the **Chainage to shift to***

OK/Apply button

OK applies the shift and removes the panel.

Apply applies the shift and leaves the panel on the screen.

Text Version of the MTF

In the text version of the mtf file, most of (a) to (h) begin with a key word, following by an equals sign (=) and then special commands enclosed in { }.

```
key_word = {
           commands
        }
```

The key words for each case above are

- (a) left_side, right_side
- (b) specials
- (c) hinge_modifier
- (d) left_side_modifier, right_side_modifier
- (e) stripping
- (f) boxing_file, left_boxing, right_boxing
- (g) section_width
- (h) string_modifiers

If any of the key words exist, then they must be in the following order in the **mtf** file:

```
left_side           = { ... }
right_side          = { ... }
specials            = { ... }
hinge_modifier      = { ... }
left_side_modifier  = { ... }
right_side_modifier = { ... }
stripping           = { ... }
boxing_file         = "something.bf"
left_boxing         = { ... }
right_boxing        = { ... }
section_width       = value
string_modifiers    = { ... }
```

The format for *boxing_file* is simply

```
boxing_file = "something.bf"
```

where *something.bf* is the name of a file containing boxing definitions to use for the mtf.

The format for (g) is simply

```
section_width = value // default is 10000
```

where *value* is the distance to search from the hinge string for strings required in some options. If *section_width* is missing, then it takes the default value of 10000.

The key words, *left_side* and *right_side* which are for initially applying templates (for part(a)), have already been described under the Design=>Apply=>Apply many option but will be summarised in the next section "Templates" .

The documentation for the **text file syntax** of the MTF file now follows.

Left Side, Right Side File Format

The file format for the `left_side` and `right_side` sections of the `mtf` file has been given in the section Apply Many of the chapter, Templates.

Summarizing, the templates on the left and right hand sides of the centre line are specified separately in the many templates file.

The left-side (right-side) definition begins with the key words

```
left_side =           right_side =
```

with a list of chainages (in ascending order, one per line) with template names. This list of chainages and templates is enclosed in curly braces `{}`.

The chainage-template lists are assembled as follows

- (a) To represent a template starting at a given chainage, the chainage value followed by the template name is given. The chainage and name are separated by one or more spaces. For example, the template `std` starting at chainage 150 is represented by

```
150      std
```

The template is assumed to apply until the chainage given on the next line of the left-side definition.

If the template is to go to the end of the centre-line, add a line with a chainage greater than or equal to the end chainage. For example,

```
150      std
99999
```

- (b) if no template exists from a chainage, simply include the chainage with no template name following it. For example, if there is no template from chainage 250, this is represented by

```
250
```

The non-existence of a template is assumed to apply until the chainage given on the next line of the left-side definition

- (c) the case of a linear change from one template to another template over a specified chainage range is represented by giving the start chainage of the linear change, followed on the same line by the start template, a comma, and the end template. For example, if the template is to vary linearly between the template `std` and the template `left`, beginning at the chainage 350, then the line in the file would be

```
350      std, left
```

The linear change takes place over the interval beginning at the chainage given on the defining line and ending at the chainage given on the next line of the left-side. Distances and percent cross-falls are interpolated linearly and slopes are interpolated on the radian value of the slope angles.

A Left and Right Side File Example

```
left_side = {
    100      std
    200      std , "left 1"
    250      "left 1"
    300
    350      std
    99999
}
right_side = {
    100      std
    200      std , right
```

```
        250      right
        300      right , std
        350      std
        400
    }
```

The `left_side` describes the situation:

1. the left-hand side of the centre-line has no template from the beginning of the centre-line until chainage 100.
2. at chainage 100, the template **std** begins and continues until chainage 200.
3. there is a linear change from the template **std** to the template **left 1** between chainage 200 and chainage 250.
4. the template **left 1** goes from chainage 250 to chainage 300.
5. there is a gap between chainage 300 and chainage 350.
6. the template **std** goes from chainage 350 to chainage 99999, or if the end chainage is smaller than 99999, to the end of the centre-line.

Specials File Format

In the many templates file, the **specials** definition begins with the key word

```
specials =
```

This is followed by a list of

(a) chainages, in any order, one per line

and/or

(b) the names of files (enclosed in quotes “”) which include lists of chainages (The default ending for a special chainage file is *.spc)

The list of chainages and/or file names is enclosed in curly braces {}.

A Specials Example

```
specials = {
    125.3
    1925.4
    “fred”           // file of chainages to read in
    3007
    “joe”
}
```

Hinge Modifier File Format

In the many templates file, the **hinge modifier** definition begins with the key word

```
hinge_modifier =
```

followed by one or more of the hinge modifier commands **offset**, **height**, **coord** and **nohinge** enclosing curly braces {}.

```
hinge_modifier = {
    hinge modifier commands
}
```

The definition of the hinge modifier commands will now be given.

Offset

The **offset** modifier will move the hinge point a given offset distance (perpendicular to the reference string) from its current plan position. A positive offset is to the right of the hinge string and a negative offset to the left.

The format of the modifier to vary the **offset** is

```
offset st_ch end_ch st_offset end_offset absrel type extra_start extra_end
```

where

st_ch start chainage for the modifier

end_ch end chainage for the modifier

st_offset offset to be used at the start modifier chainage, st_ch

end_offset offset to be used at the end modifier chainage, end_ch.

absrel relative (default) or absolute

type linear (default) or cubic

extra_start optional - adds in an extra x-section 0.1mm before start chainage

extra_end optional - adds in an extra x-section 0.1mm before end chainage

If **absrel** is **relative** (the default) then

the st_offset is added to the current position of the hinge point at chainage st_ch.

the end_offset is added to the current position of the hinge point at chainage end_ch.

If **absrel** is **absolute**, then

the offset of the hinge point is taken with respect to the original position of the hinge string at chainage st_ch.

the offset of the hinge point is taken with respect to the original position of the hinge string at chainage end_ch.

If **type** is **linear** (the default), then the offset is varied linearly (with respect to the reference chainage) between the offsets at chainage st_ch and chainage end_ch.

If **type** is **cubic**, then the offset is varied as a reverse cubic (with respect to the reference chainage) between the offsets at chainage st_ch and chainage end_ch.

Offset to String

The offset for the hinge point can also be varied by **going out to another 12d Model string**.

offset st_ch end_ch full_string_name extra_start extra_end

where

st_ch start chainage for the modifier

end_ch end chainage for the modifier

full_string_name name of a 12d Model string to take the hinge point out to. The format of the string name is "model_name->string_name".

extra_start optional - adds in an extra x-section 0.1mm before start chainage

extra_end optional - adds in an extra x-section 0.1mm before end chainage

Height

The **height** modifier varies the height of the hinge point between the given chainages.

height st_ch end_ch st_height end_height absrel type extra_start extra_end

where

st_ch start chainage for the modifier

end_ch end chainage for the modifier

st_height height to be used at the start modifier chainage, st_ch

end_height height to be used at the end modifier chainage, end_ch.

absrel relative (default) or absolute

type linear (default) or cubic

extra_start optional - adds in an extra x-section 0.1mm before start chainage

extra_end optional - adds in an extra x-section 0.1mm before end chainage

If **absrel** is **relative** (the default) then

the st_height is added to the current height of the hinge point at chainage st_ch.

the end_height is added to the current height of the hinge point at chainage end_ch.

If **absrel** is **absolute**, then

the height of the hinge point is set to st_height above the original hinge string at chainage st_ch.

the height of the hinge point is set to end_height above the original hinge string at chainage end_ch.

If **type** is **linear** (the default), then the height is varied linearly (with respect to the reference chainage) between the height at chainage st_ch and chainage end_ch.

If **type** is **cubic**, then the height is varied as a reverse cubic (with respect to the reference chainage) between the height at chainage st_ch and chainage end_ch.

Height to String

The height of the hinge point can also be specified by **taking the height from another 12d Model string**.

height st_ch end_ch full_string_name extra_start extra_end

where

st_ch start chainage for the modifier

end_ch end chainage for the modifier

full_string_name name of a 12d Model string to take the hinge point height from. The format of the string name is "model_name->string_name".

extra_start optional - adds in an extra x-section 0.1mm before start chainage

`extra_end` optional - adds in an extra x-section 0.1mm before end chainage

Coord to String

The **coord** modifier is used to replace the x, y and z position of the hinge point by the x, y and z position of **another 12d Model string** between given chainages. Hence **coord** replaces the hinge string by another string between the given chainages.

```
coord st_ch end_ch full_string_name extra_start extra_end
```

where

`st_ch` start chainage for the modifier

`end_ch` end chainage for the modifier

`full_string_name` name of the **12d Model string** used to replace the hinge string between the chainages `st_ch` and `end_ch`. The format of the string name is "model_name->string_name".

`extra_start` optional - adds in an extra x-section 0.1mm before start chainage

`extra_end` optional - adds in an extra x-section 0.1mm before end chainage

Nohinge

The **nohinge** modifier is used to **stop** the hinge string (and hence the apply) between given chainages. This will leave a gap in the strings created by the apply between the given chainages.

```
nohinge st_ch end_ch extra_start extra_end
```

where

`st_ch` start chainage to stop the apply

`end_ch` end chainage for stopping the apply

`extra_start` optional - adds in an extra x-section 0.1mm before start chainage

`extra_end` optional - adds in an extra x-section 0.1mm before end chainage

Please continue to the next section "A Hinge Modifier Example" .

A Hinge Modifier Example

```
hinge_modifier = {
    offset  0 250 0 3 // linearly offset the hinge by 0 to 3
                // over the chainage range 0 to 250.
    height 125 300 2 2 // add 2 to the hinge height
                // over the chainage range 125 to 300.
    coord  300 400 "mod->new_string" // use the position of the string
                // new_string over the chainage
                // range 300 to 400.
    nohinge 400 500 2 2 // stop the apply between the chainages
                // over the chainage range 400 to 500.
}
```

Please continue to the next section "Template Modifiers" .

Template Modifiers File Format

In the many templates file, the **template modifier** definition begins with the key word

`left_side_modifier =`

and/or

`right_side_modifier =`

followed by one or more of the template modifier commands enclosing curly braces { }

(a) insert commands

insert, insert_cut, insert_fill

(b) remove commands

remove, remove_cut, remove_fill

(c) fixed link modifiers

**width, height, xfall, xfall_crc, copy_width, copy_height, copy_xfall,
tin_height, tin_xfall**

(d) stop and start decisions commands

decision

(e) variable cut and fill link modifiers

**cut_width, cut_height, cut_slope, copy_cut_width, copy_cut_height,
copy_cut_slope, tin_cut_height, tin_cut_slope**

**fill_width, fill_height, fill_slope, copy_fill_width, copy_fill_height,
copy_fill_slope, tin_fill_height, tin_fill_slope**

(f) final cut/fill link modifiers

final_width, final_cut_slope, final_no_cut_slope

final_fill_slope, final_no_fill_slope

That is,

```
left_side_modifier = {
                    } template modifier commands
```

and/or

```
right_side_modifier = {
                      } template modifier commands
```

The definition of the template modifier commands and their file format will now be given.

Please continue to the next section "Insert Modifiers".

Insert Modifiers

Fixed Link Insert

Fixed links can be created by one of three **insert** commands by specifying either width and height, width and xfall, or height and xfall.

insert link_name colour width height **unknown** st_ch end_ch *optional*// use width, height

insert link_name colour width **unknown** xfall st_ch end_ch *optional*// use width, xfall

insert link_name colour **unknown** height xfall st_ch end_ch *optional*// use height, xfall

where **unknown** takes the place of the one of width, height or xfall not being used, and

link_name	name of the link being created
colour	colour of the link being created
width, height, xfall	width, height or xfall of the created link
st_ch	start chainage for creating the link
end_ch	end chainage for creating the link

and *optional* can be none, one or more of the following

name	if non-blank, insert before the link name in the template if blank, then append after the last link of the fixed template table
extra_start	optional - adds in an extra x-section 0.1 mm before start chainage
extra_end	optional - adds in an extra x-section 0.1 mm before end chainage

Cut and Fill Link Insert

Cut and fill links can be created by one of three **insert** commands by specifying either width and height, width and slope, or height and slope.

insert_cut link_name colour width height **unknown** st_ch end_ch *optional*// width, ht

insert_fill link_name colour width height **unknown** st_ch end_ch *optional*// width, ht

insert_cut link_name colour width **unknown** slope st_ch end_ch *optional*// width, slope

insert_fill link_name colour width **unknown** slope st_ch end_ch *optional*// width, slope

insert_cut link_name colour **unknown** height slope st_ch end_ch *optional*// ht, slope

insert_fill link_name colour **unknown** height slope st_ch end_ch *optional*// ht, slope

where **unknown** takes the place of the one of width, height or slope not being used, and

link_name	name of the link being created
colour	colour of the link being created
width, height, slope	width, height or slope of the created link
st_ch	start chainage for creating the link
end_ch	end chainage for creating the link

and *optional* can be none, one or more of the following

name	if non-blank, insert before the link name in the template if blank, then append after the last link of the fixed template table
extra_start	optional - adds in an extra x-section 0.1 mm before start chainage
extra_end	optional - adds in an extra x-section 0.1 mm before end chainage

Please continue to the next section "Remove Modifiers" .

Remove Modifiers

Fixed, cut and fill links can be deleted by one of three **remove** commands:

remove link_list st_ch end_ch *optional*

remove_cut link_list st_ch end_ch *optional*

remove_fill link_list st_ch end_ch *optional*

where

link_list one or more names of links to be removed, in the form
name1 name2 ... namei

st_ch start chainage for removing the link

end_ch end chainage for removing the link

and *optional* can be none, one or two of

extra_start optional - adds in an extra x-section 0.1 mm before start chainage

extra_end optional - adds in an extra x-section 0.1 mm before end chainage

Please continue to the next section "Fixed Link Modifiers".

Fixed Link Modifiers

Width

The **width** modifier is used to modify the width of fixed links originally defined by width.

The format of the modifier to vary the **width** of the fixed links given by link_list is

width link_list st_ch end_ch st_wid end_wid absrel type extra_start extra_end

where

link_list one or more names of fixed links given in the template definition; with format
name1 name2 ... namei

st_ch start chainage for the modifier

end_ch end chainage for the modifier

st_wid width to be used at the start modifier chainage, st_ch

end_wid width to be used at the end modifier chainage, end_ch.

absrel relative (default) or absolute

type linear (default) or cubic

extra_start optional - adds in an extra x-section 0.1mm before start chainage

extra_end optional - adds in an extra x-section 0.1mm before end chainage

If **absrel** is **relative** (the default) then

the st_wid is added to the current width of links in link_list at chainage st_ch.

the end_wid is added to the current width of links in link_list at chainage
end_ch.

If **absrel** is **absolute**, then

the width of links in link_list are set to st_wid at chainage st_ch.

the width of links in link_list are set to end_wid at chainage end_ch.

If **type** is **linear** (the default), then the width of links in link_list are varied linearly (with respect to the reference chainage) between the width at chainage st_ch and chainage end_ch.

If **type** is **cubic**, then the width of links in link_list is varied as a reverse cubic (with respect to the reference chainage) between the width at chainage st_ch and chainage end_ch.

The width for a link can also be varied by **going out to another 12d Model string** or by taking the **width between two 12d Model strings**.

width link_list st_ch end_ch full_string_name side ext_start ext_end
width link_list st_ch end_ch str_name_1 side_1 str_name_2 side_2 ext_start ext_end
 where

link_list	one or more names of fixed links given in the template definition; with format name1 name2 ... namei
st_ch	start chainage for the modifier
end_ch	end chainage for the modifier
full_string_name	name of a 12d Model string to take links in link_list out to. The format of the string name is "model_name->string_name".
side	side to search for string: -1 for left, 0 for left and right, 1 for right
ext_start	optional - adds in an extra x-section 0.1mm before start chainage
ext_end	optional - adds in an extra x-section 0.1mm before end chainage
str_name_1	name of the first 12d Model string. The format of the string name is "model_name->string_name".
side_1	side to search for string_1: -1 for left, 0 for left and right, 1 for right
str_name_2	name of the second 12d Model string. The format of the string name is "model_name->string_name".
side_2	side to search for string_2: -1 for left, 0 for left and right, 1 for right

The **width** of links in link_list are taken to be the distance between **str_name_1** and **str_name_2**.

Width from Link

The **width from link** modifier is used to modify the width of fixed links originally defined by width to be the same as another link. That is, the width of the link is a copy of the width of another link.

The format of the modifier to vary the **width from link** of the fixed links given by link_list is

copy_width link_list st_ch end_ch from_link zone extra_start extra_end
 where

link_list	one or more names of fixed links given in the template definition; with format name1 name2 ... namei
st_ch	start chainage for the modifier
end_ch	end chainage for the modifier
from_link	name of link to take the width from
zone	section of the template that the from_link is from (i.e. fixed, cut or fill)
extra_start	optional - adds in an extra x-section 0.1mm before start chainage
extra_end	optional - adds in an extra x-section 0.1mm before end chainage

Height

The **height** modifier is used to modify the height of fixed links originally defined by height.

The format of the modifier to vary the **height** of the fixed links in the **link_list** is almost identical to varying the width and is:

height link_list st_ch end_ch st_ht end_ht absrel type extra_start extra_end
where

link_list one or more names of fixed links given in the template definition; with format name1 name2 ... namei
st_ch start chainage for the modifier
end_ch end chainage for the modifier
st_ht height to be used at the start modifier chainage, st_ch
end_wid height to be used at the end modifier chainage, end_ch.
absrel relative (default) or absolute
type linear (default) or cubic
extra_start optional - adds in an extra x-section 0.1mm before start chainage
extra_end optional - adds in an extra x-section 0.1mm before end chainage

If **absrel** is **relative** (the default) then

the st_ht is added to the current height of links in link_list at chainage st_ch.
the end_ht is added to the current height of links in link_list at chainage end_ch.

If **absrel** is **absolute**, then

the height of links in link_list are set to st_ht at chainage st_ch.
the height of links in link_list are set to end_ht at chainage end_ch.

If **type** is **linear** (the default), then the height of links in link_list are varied linearly (with respect to the reference chainage) between the height at chainage st_ch and chainage end_ch.

If **type** is **cubic**, then the height of links in link_list is varied as a reverse cubic (with respect to the reference chainage) between the height at chainage st_ch and chainage end_ch.

The height for a link can also be varied by **taking the height from a 12d Model string** or by taking the **height between two 12d Model strings**.

height link_list st_ch end_ch full_string_name side extra_start extra_end
height link_list st_ch end_ch str_name_1 side1 str_name_2 side2 extra_start extra_end
where

link_list one or more names of fixed links given in the template definition; with format name1 name2 ... namei
st_ch start chainage for the modifier
end_ch end chainage for the modifier
full_string_name name of a 12d Model string to take links in link_list out to. The format of the string name is "model_name->string_name".
side side to search for string: -1 for left, 0 for left and right, 1 for right
extra_start optional - adds in an extra x-section 0.1mm before start chainage
extra_end optional - adds in an extra x-section 0.1mm before end chainage
str_name_1 name of the first 12d Model string. The format of the string name is "model_name->string_name".
side2 side to search for string: -1 for left, 0 for left and right, 1 for right
str_name_2 name of the second 12d Model string. The format of the string name is "model_name->string_name".
side2 side to search for string: -1 for left, 0 for left and right, 1 for right
The **height** of links in link_list are taken to be the height between **str_name_1** and **str_name_2**.

Height from Link

The **height from link** modifier is used to modify the height of fixed links originally defined by height to be the same height as another link. That is, the height of the link is a copy of the height of another link.

The format of the modifier to vary the **height from link** of the fixed links given by link_list is

copy_height link_list st_ch end_ch from_link zone extra_start extra_end

where

link_list	one or more names of fixed links given in the template definition; with format name1 name2 ... namei
st_ch	start chainage for the modifier
end_ch	end chainage for the modifier
from_link	name of link to take the height from
zone	section of the template that the from_link is from (i.e. fixed, cut or fill)
extra_start	optional - adds in an extra x-section 0.1mm before start chainage
extra_end	optional - adds in an extra x-section 0.1mm before end chainage

Cross Fall

The **xfall** modifier is used to modify the cross fall of fixed links originally defined by xfall.

The format of the modifier to vary the cross-fall of the fixed links in the **link_list** is almost identical to varying the width and is:

xfall link_list st_ch end_ch st_xfall end_xfall absrel type extra_start extra_end

where

link_list	one or more names of fixed links given in the template definition; with format name1 name2 ... namei
st_ch	start chainage for the modifier
end_ch	end chainage for the modifier
st_xfall	xfall to be used at the start modifier chainage, st_ch
end_xfall	xfall to be used at the end modifier chainage, end_ch.
absrel	relative (default) or absolute
type	linear (default) or cubic
extra_start	optional - adds in an extra x-section 0.1mm before start chainage
extra_end	optional - adds in an extra x-section 0.1mm before end chainage

If **absrel** is **relative** (the default) then

the st_xfall is added to the current xfall of links in link_list at chainage st_ch.

the end_xfall is added to the current xfall of links in link_list at chainage end_ch.

If **absrel** is **absolute**, then

the xfall of links in link_list are set to st_xfall at chainage st_ch.

the xfall of links in link_list are set to end_xfall at chainage end_ch.

If **type** is **linear** (the default), then the xfall of links in link_list are varied linearly (with respect to the reference chainage) between the xfall at chainage st_ch and chainage end_ch.

cubic, then the xfall of links in link_list are varied as a reverse cubic (with respect to the reference chainage) between the xfall at chainage st_ch and chainage end_ch.

rotate, then the angle of the xfall of the links in link_list is varied linearly (with respect to the reference chainage) between the angle of the xfall at chainage st_ch and chainage end_ch.

The **xfall** of a link can be defined by using the xfall from the **beginning of the link** (i.e. the end of the previous link or the hinge string if it is the first link) **to another 12d Model string**, or by taking the **xfall between two 12d Model strings**.

```
xfall link_list st_ch end_ch full_string_name side extra_start extra_end
xfall link_list st_ch end_ch str_name_1 side1 str_name_2 side2 extra_start extra_end
```

where

link_list	one or more names of fixed links given in the template definition; with format name1 name2 ... namei
st_ch	start chainage for the modifier
end_ch	end chainage for the modifier
full_string_name	name of a 12d Model string to use to calculate xfall. The format of the string name is "model_name->string_name".
side	side to search for string: -1 for left, 0 for left and right, 1 for right
extra_start	optional - adds in an extra x-section 0.1mm before start chainage
extra_end	optional - adds in an extra x-section 0.1mm before end chainage
str_name_1	name of the first 12d Model string. The format of the string name is "model_name->string_name".
side1	side to search for string_1: -1 for left, 0 for left and right, 1 for right
str_name_2	name of the second 12d Model string.
side2	side to search for string_2: -1 for left, 0 for left and right, 1 for right

The **xfall** of links in link_list are taken to be the xfall between **str_name_1** and **str_name_2**.

Cross Fall Circular Reverse Curve

The **xfall_crc** modifier is used to modify the cross fall of fixed links originally defined by **xfall** using the circular reverse curve formula.

The format of the modifier to vary the cross-fall of the fixed links (using circular reverse curves) in the **link_list** is:

```
xfall_crc link_list st_ch end_ch st_xfall end_xfall st_len end_len extra_start extra_end
```

where

link_list	one or more names of fixed links given in the template definition; with format name1 name2 ... namei
st_ch	start chainage for the modifier
end_ch	end chainage for the modifier
st_xfall	xfall to be used at the start modifier chainage, st_ch
end_xfall	xfall to be used at the end modifier chainage, end_ch.
st_len	length of the start circular arc to be used at the start modifier chainage, st_ch.
end_len	length of the end circular arc to finish at the end modifier chainage, st_ch.
extra_start	optional - adds in an extra x-section 0.1mm before start chainage
extra_end	optional - adds in an extra x-section 0.1mm before end chainage

Xfall from Link

The **xfall from link** modifier is used to modify the xfall of fixed links originally defined by xfall to be the same xfall as another link. That is, the xfall of the link is a copy of the xfall of another link.

The format of the modifier to vary the **xfall from link** of the fixed links given by link_list is

copy_xfall link_list st_ch end_ch from_link zone extra_start extra_end

where

link_list one or more names of fixed links given in the template definition; with format name1 name2 ... namei

st_ch start chainage for the modifier

end_ch end chainage for the modifier

from_link name of the link to take the xfall from

zone section of the template that the from_link is from (i.e. fixed, cut or fill)

extra_start optional - adds in an extra x-section 0.1mm before start chainage

extra_end optional - adds in an extra x-section 0.1mm before end chainage

Important Note

The link to copy cross fall from can be defined in terms of cross fall or slope.

If the link to copy is defined by slope, then the cross fall is calculated to match the slope.

Tin Height

The **tin height** modifier is used to modify the height of the link so that the link will sit on the tin at the given width.

The tin height can only be used for a fixed link defined by width and height.

The format of the modifier to vary the **tin height** of the fixed links in the **link_list** is:

tin_height link_list st_ch end_ch tin_name extra_start extra_end

where

link_list one or more names of fixed links given in the template definition; with format name1 name2 ... namei

st_ch start chainage for the modifier

end_ch end chainage for the modifier

tin_name name of the tin to be used in defining the height.

extra_start optional - adds in an extra x-section 0.1mm before start chainage

extra_end optional - adds in an extra x-section 0.1mm before end chainage

Tin Xfall

The **tin xfall** modifier is used to modify the xfall of the link so that the link will sit on the tin at the given width.

The tin xfall can only be used for a fixed link defined by width and xfall.

The format of the modifier to vary the **tin xfall** of the fixed links in the **link_list** is:

tin_xfall link_list st_ch end_ch tin_name extra_start extra_end

where

link_list one or more names of fixed links given in the template definition; with format name1 name2 ... namei

st_ch start chainage for the modifier

end_ch end chainage for the modifier

tin_name name of the tin to be used in defining the xfall.

extra_start optional - adds in an extra x-section 0.1mm before start chainage

extra_end optional - adds in an extra x-section 0.1mm before end chainage

Please continue to the next section "Decision".

Decision

Each template is made up of the sections fixed, decisions, cut, fill and final cut/fill. If a template has a decisions section then by default it is used instead of the cut, fill and final cut/fill sections.

Hence by default, either the
decisions section

or

the cut, fill and final cut/fill sections

from the template being used over the chainage range.

Using the **decision** modifier, it is possible to override the default and for a given chainage range use the cut, fill and final cut/fill sections **instead** of the decisions section

or

use the decisions section **from another** template instead of the current templates sections.

The format of the decision modifier is

decision template_name st_ch end_ch *optional*

decision " " st_ch end_ch *optional*

where

template_name name of template to take the decision section from.

If the template name is given as " ", then the decision section for the template being used in the chainage range is ignored, and the cut, fill and final cut/fill tables for the template are used instead. Hence this overrides the default of using the decisions section in preference to the cut, fill and final cut/fill sections of the template.

st_ch start chainage for applying/removing the decision

end_ch end chainage for applying/removing the decision

and *optional* can be none, one or two of

extra_start optional - adds in an extra x-section 0.1 mm before start chainage

extra_end optional - adds in an extra x-section 0.1 mm before end chainage

Note

The full description of the **decisions** section of a template is given later in this chapter.

Please continue to the next section "Variable Link Modifiers".

Variable Link Modifiers

Cut and Fill Width

The **cut_width** modifier is used to modify the width of variable cut links originally defined by width. Similarly the **fill_width** modifier is used to modify the width of variable fill links originally defined by width.

The format of the modifier to vary the width of the variable cut/fill links in **link_list** is

cut_width link_list st_ch end_ch st_wid end_wid absrel type extra_start extra_end
fill_width link_list st_ch end_ch st_wid end_wid absrel type extra_start extra_end

where

<code>link_list</code>	one or more names of cut/fill links given in the template definition; with format <code>name1 name2 ... namei</code>
<code>st_ch</code>	start chainage for the modifier
<code>end_ch</code>	end chainage for the modifier
<code>st_wid</code>	width to be used at the start modifier chainage, <code>st_ch</code>
<code>end_wid</code>	width to be used at the end modifier chainage, <code>end_ch</code> .
<code>absrel</code>	relative (default) or absolute
<code>type</code>	linear (default) or cubic
<code>extra_start</code>	optional - adds in an extra x-section 0.1mm before start chainage
<code>extra_end</code>	optional - adds in an extra x-section 0.1mm before end chainage

If **absrel** is **relative** (the default) then

the `st_wid` is added to the current width of links in `link_list` at chainage `st_ch`.
the `end_wid` is added to the current width of links in `link_list` at chainage `end_ch`.

If **absrel** is **absolute**, then

the width of links in `link_list` are set to `st_wid` at chainage `st_ch`.
the width of links in `link_list` are set to `end_wid` at chainage `end_ch`.

If **type** is **linear** (the default), then the width of links in `link_list` are varied linearly (with respect to the reference chainage) between the width at chainage `st_ch` and chainage `end_ch`.

If **type** is **cubic**, then the width of links in `link_list` are varied as a reverse cubic (with respect to the reference chainage) between the width at chainage `st_ch` and chainage `end_ch`.

The **width** for a variable link can also be varied by **going out to another 12d Model string**.

cut_width `link_list st_ch end_ch full_string_name side extra_start extra_end`
fill_width `link_list st_ch end_ch full_string_name side extra_start extra_end`

where

<code>link_list</code>	one or more names of cut/fill links given in the template definition; with format <code>name1 name2 ... namei</code>
<code>st_ch</code>	start chainage for the modifier
<code>end_ch</code>	end chainage for the modifier
<code>full_string_name</code>	name of a 12d Model string to take links in <code>link_list</code> out to. The format of the string name is "model_name->string_name".
<code>side</code>	side to search for string: -1 for left, 0 for left and right, 1 for right
<code>extra_start</code>	optional - adds in an extra x-section 0.1mm before start chainage
<code>extra_end</code>	optional - adds in an extra x-section 0.1mm before end chainage

The **width** for a link can also be varied by using the **width between two 12d Model strings** `str_name_1` and `str_name_2`.

cut_width `link_list st_ch end_ch str_name_1 side1 str_name_2 side2 extra_start extra_end`
fill_width `link_list st_ch end_ch str_name_1 side1 str_name_2 side2 extra_start extra_end`

Cut and Fill Width from Link

The cut and fill **width from link** modifiers are used to modify the width of cut and fill links originally defined by width, to be the same as another link. That is, the width of the link is a copy of the width of another link.

The format of the modifier to vary the cut and fill **width from link** of the fixed links given by `link_list` is

copy_cut_width link_list st_ch end_ch from_link zone extra_start extra_end
copy_fill_width link_list st_ch end_ch from_link zone extra_start extra_end

where

link_list one or more names of fixed links given in the template definition; with format name1 name2 ... namei
st_ch start chainage for the modifier
end_ch end chainage for the modifier
from_link name of the link to take the width from
zone section of the template that the from_link is from (i.e. fixed, cut or fill)
extra_start optional - adds in an extra x-section 0.1mm before start chainage
extra_end optional - adds in an extra x-section 0.1mm before end chainage

Cut and Fill Height

The **cut_height** modifier is used to modify the height of variable cut links originally defined by height. Similarly the **fill_height** modifier is used to modify the height of variable fill links originally defined by height.

The format of the modifier to vary the height of the variable cut/fill links in **link_list** is

cut_height link_list st_ch end_ch st_ht end_ht absrel type extra_start extra_end
fill_height link_list st_ch end_ch st_ht end_ht absrel type extra_start extra_end

where

link_list one or more names of cut/fill links given in the template definition; with format name1 name2 ... namei
st_ch start chainage for the modifier
end_ch end chainage for the modifier
st_ht height to be used at the start modifier chainage, st_ch
end_ht height to be used at the end modifier chainage, end_ch.
absrel relative (default) or absolute
type linear (default) or cubic
extra_start optional - adds in an extra x-section 0.1mm before start chainage
extra_end optional - adds in an extra x-section 0.1mm before end chainage

If **absrel** is **relative** (the default) then

the st_ht is added to the current height of links in link_list at chainage st_ch.
the end_ht is added to the current height of links in link_list at chainage end_ch.

If **absrel** is **absolute**, then

the height of links in link_list are set to st_ht at chainage st_ch.
the height of links in link_list are set to end_ht at chainage end_ch.

If **type** is **linear** (the default), then the height of links in link_list are varied linearly (with respect to the reference chainage) between the height at chainage st_ch and chainage end_ch.

If **type** is **cubic**, then the height of links in link_list are varied as a reverse cubic (with respect to the reference chainage) between the height at chainage st_ch and chainage end_ch.

The **height** for a variable link can also be varied by **taking the height from a 12d Model string**.

cut_height link_list st_ch end_ch full_string_name side extra_start extra_end
fill_height link_list st_ch end_ch full_string_name side extra_start extra_end

where

link_list	one or more names of cut/fill links given in the template definition; with format name1 name2 ... namei
st_ch	start chainage for the modifier
end_ch	end chainage for the modifier
full_string_name	name of a 12d Model string to take links in link_list out to. The format of the string name is "model_name->string_name".
side	side to search for string: -1 for left, 0 for left and right, 1 for right
extra_start	optional - adds in an extra x-section 0.1mm before start chainage
extra_end	optional - adds in an extra x-section 0.1mm before end chainage

The **height** for a link can also be varied by using the **height between two 12d Model strings str_name_1 and str_name_2**.

cut_height link_list st_ch end_ch str_name_1 side1 str_name_2 side2 extra_start extra_end
fill_height link_list st_ch end_ch str_name_1 side1 str_name_2 side2 extra_start extra_end

Cut and Fill Height from Link

The cut and fill **height from link** modifiers are used to modify the height of cut and fill links originally defined by height, to be the same as another link. That is, the height of the link is a copy of the height of another link.

The format of the modifier to vary the cut and fill **height from link** of the fixed links given by link_list is

copy_cut_height link_list st_ch end_ch from_link zone extra_start extra_end
copy_fill_height link_list st_ch end_ch from_link zone extra_start extra_end

where

link_list	one or more names of fixed links given in the template definition; with format name1 name2 ... namei
st_ch	start chainage for the modifier
end_ch	end chainage for the modifier
from_link	name of the link to take the height from
zone	section of the template that the from_link is from (i.e. fixed, cut or fill)
extra_start	optional - adds in an extra x-section 0.1mm before start chainage
extra_end	optional - adds in an extra x-section 0.1mm before end chainage

Cut and Fill Slope

The **cut_slope** modifier is used to modify the slope of variable cut links originally defined by slope. Similarly the **fill_slope** modifier is used to modify the slope of variable fill links originally defined by slope.

The format of the modifier to vary the cut/fill slope of the variable links in **link_list** is

cut_slope link_list st_ch end_ch st_slope end_slope absrel type extra_start extra_end
fill_slope link_list st_ch end_ch st_slope end_slope absrel type extra_start extra_end

where

link_list	one or more names of cut/fill links given in the template definition; with format name1 name2 ... namei
st_ch	start chainage for the modifier
end_ch	end chainage for the modifier
st_slope	slope to be used at the start modifier chainage, st_ch
end_slope	slope to be used at the end modifier chainage, end_ch.
absrel	relative (default) or absolute
type	linear (default) or cubic
extra_start	optional - adds in an extra x-section 0.1mm before start chainage
extra_end	optional - adds in an extra x-section 0.1mm before end chainage

If **absrel** is **relative** (the default) then

the **st_slope** is added to the current slope of links in **link_list** at chainage **st_ch**.
the **end_slope** is added to the current slope of links in **link_list** at chainage **end_ch**.

If **absrel** is **absolute**, then

the slope of links in **link_list** is set to **st_slope** at chainage **st_ch**.
the slope of links in **link_list** is set to **end_slope** at chainage **end_ch**.

If **type** is **linear** (the default), then the slope of links in **link_list** is varied linearly (with respect to the reference chainage) between the slope at chainage **st_ch** and chainage **end_ch**.

cubic, then the angle of the slope of links in **link_list** are varied as a reverse cubic (with respect to the reference chainage) between the angle of the slope at chainage **st_ch** and chainage **end_ch**.

rotate, then the angle of the slope of the links in **link_list** are varied linearly (with respect to the reference chainage) between the angle of the slope at chainage **st_ch** and chainage **end_ch**.

The **slope** of a link can also be defined by using the slope from the **beginning of the link** (i.e. the end of the previous link or the hinge string if its the first link) to a given **12d** Model string.

cut_slope link_list st_ch end_ch full_string_name side extra_start extra_end
fill_slope link_list st_ch end_ch full_string_name side extra_start extra_end

where

link_list	one or more names of cut/fill links given in the template definition; with format name1 name2 ... namei
st_ch	start chainage for the modifier
end_ch	end chainage for the modifier
full_string_name	name of a 12d Model string to use to calculate slope. The format of the string name is "model_name->string_name".
side	side to search for string: -1 for left, 0 for left and right, 1 for right
extra_start	optional - adds in an extra x-section 0.1mm before start chainage

`extra_end` optional - adds in an extra x-section 0.1mm before end chainage

The **slope** of a link can also be defined by using the slope **between two 12d Model strings** `str_name_1` and `str_name_2`.

`cut_slope link_list st_ch end_ch str_name_1 side1 str_name_2 side2 extra_start extra_end`
`fill_slope link_list st_ch end_ch str_name_1 side1 str_name_2 side2 extra_start extra_end`

Cut and Fill Slope from Link

The cut and fill **slope from link** modifiers are used to modify the slope of cut and fill links originally defined by slope, to be the same **slope** or **xfall** as another link. That is, the slope of the link is a copy of the slope of another link.

The format of the modifier to vary the cut and fill **slope from link** of the fixed links given by `link_list` is

`copy_cut_slope link_list st_ch end_ch from_link zone extra_start extra_end`
`copy_fill_slope link_list st_ch end_ch from_link zone extra_start extra_end`

where

`link_list` one or more names of fixed links given in the template definition; with format `name1 name2 ... namei`
`st_ch` start chainage for the modifier
`end_ch` end chainage for the modifier
`from_link` name of the link to take the slope or xfall from
`zone` section of the template that the `from_link` is from (i.e. fixed, cut or fill)
`extra_start` optional - adds in an extra x-section 0.1mm before start chainage
`extra_end` optional - adds in an extra x-section 0.1mm before end chainage

Important Note

The link to copy slope from can be defined in terms of slope or **cross fall**.

If the link to copy is defined by cross fall, then the slope is calculated to match the cross fall.

Hence this command can be used with cut and fill slopes to match to rotation of cross fall of fixed links for super-elevation.

Cut and Fill Tin Height

The **cut and fill tin height** modifiers are used to modify the height of the link so that the link will sit on the tin at the given width.

The tin height can only be used for a cut or fill link defined by width and height.

The format of the modifiers to vary the **cut and fill tin height** of the links in the `link_list` are:

`tin_cut_height link_list st_ch end_ch tin_name extra_start extra_end`
`tin_fill_height link_list st_ch end_ch tin_name extra_start extra_end`

where

`link_list` one or more names of cut/fill links given in the template definition; with format `name1 name2 ... namei`
`st_ch` start chainage for the modifier
`end_ch` end chainage for the modifier
`tin_name` name of the tin to be used in defining the height.
`extra_start` optional - adds in an extra x-section 0.1mm before start chainage
`extra_end` optional - adds in an extra x-section 0.1mm before end chainage

Cut and Fill Tin Slope

The **cut and fill tin slope** modifier is used to modify the slope of the link so that the link will sit on the tin at the given width.

The cut and fill tin slope can only be used for a cut/fill link defined by width and slope.

The format of the modifiers to vary the **cut and fill tin slope** of the links in the **link_list** are:

```
tin_cut_slope link_list st_ch end_ch tin_name extra_start extra_end
tin_fill_slope link_list st_ch end_ch tin_name extra_start extra_end
```

where

link_list one or more names of fixed links given in the template definition; with format name1 name2 ... namei

st_ch start chainage for the modifier

end_ch end chainage for the modifier

tin_name name of the tin to be used in defining the slope.

extra_start optional - adds in an extra x-section 0.1mm before start chainage

extra_end optional - adds in an extra x-section 0.1mm before end chainage

Please continue to the next section "Final Link Modifiers" .

Final Link Modifiers

Final Width

The format of the modifier to **vary the width** of the final cut and fill link **link_name** is

```
final_width link_name st_ch end_ch st_wid end_wid absrel type extra_start extra_end
```

where

link_name name of final link given in the template definition

st_ch start chainage for the modifier

end_ch end chainage for the modifier

st_wid width to be used at the start modifier chainage, **st_ch**

end_wid width to be used at the end modifier chainage, **end_ch**.

absrel relative (default) or absolute

type linear (default) or cubic

extra_start optional - adds in an extra x-section 0.1mm before start chainage

extra_end optional - adds in an extra x-section 0.1mm before end chainage

If **absrel** is **relative** (the default) then

the **st_wid** is added to the current width of **link_name** at chainage **st_ch**.

the **end_wid** is added to the current width of **link_name** at chainage **end_ch**.

If **absrel** is **absolute**, then

the width of **link_name** is set to **st_wid** at chainage **st_ch**.

the width of **link_name** is set to **end_wid** at chainage **end_ch**.

If **type** is **linear** (the default), then the width of **link_name** is varied linearly (with respect to the reference chainage) between the width at chainage **st_ch** and chainage **end_ch**.

If **type** is **cubic**, then the width of **link_name** is varied as a reverse cubic (with respect to the reference chainage) between the width at chainage **st_ch** and chainage **end_ch**.

Final Cut and Fill Slope

The format of the modifier to vary the cut/fill slope of the final link **link_name** is

final_cut_slope link_name st_ch end_ch st_slope end_slope absrel type ext_st ext_end
final_fill_slope link_name st_ch end_ch st_slope end_slope absrel type ext_st ext_end

where

link_name	name of final link given in the template definition
st_ch	start chainage for the modifier
end_ch	end chainage for the modifier
st_slope	slope to be used at the start modifier chainage, st_ch
end_slope	slope to be used at the end modifier chainage, end_ch.
absrel	relative (default) or absolute
type	linear (default) or cubic
ext_st	optional - adds in an extra x-section 0.1mm before start chainage
ext_end	optional - adds in an extra x-section 0.1mm before end chainage

If **absrel** is **relative** (the default) then

the st_slope is added to the current slope of link_name at chainage st_ch.

the end_slope is added to the current slope of link_name at chainage end_ch.

If **absrel** is **absolute**, then

the slope of link_name is set to st_slope at chainage st_ch.

the slope of link_name is set to end_slope at chainage end_ch.

If **type** is **linear** (the default), then the slope of link_name is varied linearly (with respect to the reference chainage) between the slope at chainage st_ch and chainage end_ch.

cubic, then the angle of the slope of link_name is varied as a reverse cubic (with respect to the reference chainage) between the angle of the slope at chainage st_ch and chainage end_ch.

Stopping Final Cut and Fill Slope

The final link can be stopped altogether in either cut or fill.

The format of the modifier to stop the cut/fill slope of the final link link_name is

final_no_cut_slope link_name st_ch end_ch extra_start extra_end
final_no_fill_slope link_name st_ch end_ch extra_start extra_end

where

link_name	name of final link given in the template definition
st_ch	start chainage for the final link to stop
end_ch	end chainage for the final link to stop
extra_start	optional - adds in an extra x-section 0.1mm before start chainage
extra_end	optional - adds in an extra x-section 0.1mm before end chainage

Please continue to the next section "A Template Modifier File Example".

A Template Modifier File Example

```
left_side = {
  -99999.9  "std"
  99999.9
}

right_side = {
  -99999.9  "std"
  99999.9
}
```

```

//                                     -- assumes ---
left_side_modifier = {
  width "kerb" 103 203.0 0.0 3.0 absolute linear // widen from width 0 to width 3 - linear
  width "kerb" 203.0 303.0 3.0 3.0 absolute // keep width at 3
  width "kerb" 303.0 403.0 3.0 0.0 absolute // widen from width 3 to width 0 - linear
  width "kerb" 153.0 253.0 0.0 9.0 cubic relative
  width "kerb" 253.0 353.0 9.0 0.0 cubic // relative is default
  xfall "kerb" 53.0 153.0 0.0 6.0 relative linear
  xfall "kerb" 153.0 353.0 6.0 6.0 relative // linear
  xfall "kerb" 353.0 453.0 6.0 0.0 // relative & linear
  width "kerb" 440.0 480.0 "table drain->table drain" extra_start extra_end

}

```

Stripping File Format

The stripping depth is given in the many templates file (*.mtf) and is similar to the format for applying templates except there is no separate left and right side.

The stripping definition begins with the key words

```
stripping =
```

A list of chainages (in ascending order, one per line) with corresponding stripping depth then follows. The list of chainages and stripping depths is enclosed in curly braces {}.

The chainage-stripping lists are assembled as follows

- (a) to represent a stripping depth starting at a given chainage, the chainage value followed by the stripping depth is given. The chainage and stripping depth are separated by one or more spaces. For example, the stripping depth **0.03** starting at chainage 150 is represented by

```
150           0.03
```

The stripping depth is assumed to apply until the chainage given on the next line of the stripping definition.

If the stripping depth is to go to the end of the reference string, add a line with a chainage greater than or equal to the end chainage. For example

```
150           0.03
9999          0.0
```

Warning - unlike applying templates, a stripping depth **must exist** after a chainage, however the stripping depth can be zero.

- (b) linearly varying stripping depth between chainages is represented by giving the **start chainage** for the variation followed on the same line by the **start depth** and the **end depth** separated by a comma.

The linear change takes place over the interval beginning at this chainage and ending at the chainage given on the next line of the stripping definition.

For example, to linearly vary the stripping depth from 0.02 to 0.03 between the chainages 350 and 500, use

```
350           0.02 , 0.03
500           0.03
```

A Stripping Example

An example of a stripping command is

```
stripping = {
                -999      0.03
                30       0.0
                70       0.03,0.05
                110.5    0.05
                999      0.05
            }
```

Boxing File Format

Apart from a key word specifying whether the following part of the definition is for the left or the right, the set out for the left boxing is identical to the right boxing. Hence only the left boxing will be described in detail.

The left boxing definition begins with the key words

```
left_boxing =
```

A list of chainages (in ascending order, one per line) with corresponding boxing names then follows. The list of chainages and boxing is enclosed in curly braces { }.

The chainage-boxing lists are assembled as follows

- (a) to represent a boxing starting at a given chainage, the chainage value followed by the boxing name is given. The chainage and boxing name are separated by one or more spaces.

For example, the boxing **left** starting at chainage 150 is represented by

```
150      left
```

The boxing is assumed to apply until the chainage given on the next line of the `left_boxing` definition.

- (b) if no boxing exists from a chainage, simply include the chainage with no boxing name following it. For example, if there is no boxing from chainage 250, this is represented by

```
250
```

The non-existence of boxing is assumed until the chainage given on the next line of the `left_side` definition.

If the boxing is to go to the end of the reference string, add a line with a chainage greater than or equal to the end chainage. For example

```
150      left
9999
```

When using the **apply many** option, the name of the boxing definitions file is given by a **boxing_file** command in the **many templates file**.

```
boxing_file =      boxing_definitions_file
```

When using the **boxing many** option, if a file name is given in the **boxing file** panel field, it is used for the boxing definitions file, otherwise the `boxing_file` command in the many templates file is used.

Note - if the boxing name includes spaces, then the name must be enclosed in quotes ". For example, "left 1".

An Applying Boxing Example

```
boxing_file = "boxing_for_client.bf"
left_boxing = {
                -999      left
                30
                70        "left narrow"
                110.5     left
                999
            }
right_boxing = {
                -999      right
                30
                70        "right narrow"
                110.5     right
                999
            }
```

Warning - no interpolation or modifiers exist for boxing.

Width File Format

The format for **section width** in the mtf file is simply

```
section_width = value // default is 10000
```

where *value* is the distance to search from the hinge string for strings required in some options. If `section_width` is missing, then it takes the default value of 10000.

For example

```
section_width = 100.0
```

String Modifiers File Format

In the many templates file, the **string modifiers** definition begins with the key word

```
string_modifiers =
```

followed by one or more occurrences of the string modifier command **height** enclosed by curly braces { }

The definition of the string modifier commands will now be given.

Height

The *height* the Height string modifier calculates for the amend point is given by:

- (a) if the absolute flag is not set, the height of the hinge point, otherwise zero.
plus
- (b) the interpolated height for the user given heights at the start and end chainages
plus
- (c) the interpolated height for the user given cross falls at the start and end chainage.

That is, if the absolute flag is not set:

$$\mathbf{new\ height} = \text{hinge height} + (\text{interpolated height}) + (\text{interpolated xfall}) \times (\text{offset distance})$$

If the absolute flag is set:

$$\mathbf{new\ height} = (\text{interpolated height}) + (\text{interpolated xfall}) \times (\text{offset distance})$$

The format of the Height string modifier is

height amend_str ref_str hinge_str st_ch end_ch ch_int st_xfall end_xfall st_ht end_ht absolute

where

amend_str	name of a 12d Model string to take the hinge point out to. The format of the string name is "model_name->string_name".
ref_str	name of reference string. The format of the string name is "model_name->string_name".
hinge_str	name of hinge string. The format of the string name is "model_name->string_name".
st_ch	start chainage for the modifier
end_ch	end chainage for the modifier
ch_int	interval between chainage points - can be the word <i>null</i>
st_xfall	xfall to be used at the start modifier chainage, st_ch
end_xfall	xfall to be used at the end modifier chainage, end_ch.
st_ht	height to be used at the start modifier chainage, st_ch
end_ht	height to be used at the end modifier chainage, end_ch.
absolute	<i>optional</i> - if it exists, include the height of the hinge string

Height and Two Strings

The *height* the Height 2x string modifier calculates for the amend point is given by:

(a) the height of the hinge point

plus

(b) the offset distance multiplied by the cross fall between two user selected strings.

$$\text{new height} = \text{hinge height} + (\text{xfall between string 1 and string 2}) \times (\text{offset distance})$$

The format of the Height 2x string modifier is

height amend_str ref_str hinge_str st_ch end_ch ch_int xfall_str1 xfall_str2

where

amend_str name of a 12d Model string to take the hinge point out to. The format of the string name is "model_name->string_name".

ref_str name of reference string. The format of the string name is "model_name->string_name".

hinge_str name of hinge string. The format of the string name is "model_name->string_name".

st_ch start chainage for the modifier

end_ch end chainage for the modifier

ch_int interval between chainage points - can be the word *null*

xfall_str_1 name of first string to calculate cross fall between. The format of the string name is "model_name->string_name".

xfall_str_2 name of second string to calculate cross fall between. The format of the string name is "model_name->string_name".

Substitutions in the Many Templates File

The **many template variables** are special variables standing for information about the reference string used in the apply many operation.

The many template variables are only evaluated when the many template file is used in an **apply many** operation and provide a mechanism to generalize the many template file.

The many template file also recognizes the CCCP preprocessor rules including #include, #define, #if etc.

Many Template Variables

The list of the many template variables is:

\$tangent_curve_n	chainage of the tangent curve point for the nth HIP
\$tangent_spiral_n	tangent spiral
\$curve_spiral_n	curve spiral
\$spiral_curve_n	spiral curve
\$curve_spiral_n	curve spiral
\$spiral_tangent_n	spiral tangent
\$curve_tangent_n	curve tangent
\$start_spiral_n	length of the start spiral on the nth HIP point
\$end_spiral_n	length of the end spiral
\$radius_n	absolute radius of the curve
\$signed_radius_n	signed radius of the curve
\$vertical_tangent_curve_n	chainage of the tangent curve point for the nth VIP
\$vertical_curve_tangent_n	chainage of the curve tangent point for the nth VIP
\$vertical_sag_n	chainage of the sag point for the nth HIP
\$vertical_crest_n	crest
\$vertical_crest_sag_n	crest or sag

For example,

\$tangent_spiral_3 get the chainage for the tangent spiral on HIP 3.

The variables can be used in expressions with the arithmetic operations +, -, * and / as long as the expression is surrounded by round brackets ().

For example, in the width command:

```
width E ($tangent_spiral_2 - 50) ($tangent_spiral_2 + 50) 3 5 absolute
```

the expression (\$tangent_spiral_2 - 50) will yield the chainage of fifty metres before the tangent spiral point of the second HIP point.

The variables can also be used in #define's and #include's according to the following CCCP rules.

(a) **#define** *NAME* *Expansion of NAME*

if the #define is longer than one line, the backslash character \ is added to the end of each line that has another line of the #define following to indicate that the #define continues to the next line.

- (b) **#define** can be used to define a block of things with more than one argument

For example,

```
#define SUPER(name,ip,xf1,xf2) \
\
xfall name START_TAPER(ip) xf1 xf2 absolute \
xfall name FIXED_TAPER(ip) xf2 xf2 absolute \
xfall name END_TAPER(ip) xf2 xf1 absolute
```

means that SUPER("EB",3,-3.0,3.0) will be expanded to the three lines:

```
xfall "EB" START_TAPER(3) -3.0 3.0 absolute
xfall "EB" FIXED_TAPER(3) 3.0 3.0 absolute
xfall "EB" END_TAPER(3) 3.0 -3.0 absolute
```

Note that \ is used to indicate that the #define continues to the next line.

- (c) **(if (express) {expression1} else {expression 2})**

is an expression *express*, which evaluates to

if *express* is true, then the value of the expression is *expression1* otherwise *expression 2*.

- (d) **word##p**

is equivalent to **wordp**

- (e) **#include file_name**

A number of #defines can be placed in a file and included in the mtf by using the #include.

As an example combining the above rules, the meaning of

```
LEADING_TAPER_START(2)
```

given by the following \$define:

```
#define LEADING_TAPER_START(ip) ( if($radius_##ip < 75) {$tangent_spiral_##ip - 50}\
else { $tangent_spiral_##ip - 75 } )
```

is

if the radius of the second HIP is less than 75, then set LEADING_TAPER_START(2) to the chainage of the tangent spiral point of the second HIP point, less fifty metres, **otherwise** LEADING_TAPER_START(2) is set to the chainage of the tangent spiral point of the second HIP point, less seventy five metres

A more complicated example now follows which shows how #defines can be used to easily apply super-elevation according to rules involving leading and trailing spirals.

```
// -----
#define LEADING_TAPER_START(ip) ( if($radius_##ip < 75)\
{ $tangent_spiral_##ip - 50 } else { $tangent_spiral_##ip - 75 } )

// Note: LEADING_TAPER_START evaluates to a chainage.

#define LEADING_TAPER_END(ip) ( if($radius_##ip < 75)\
{ $tangent_spiral_##ip + 10 } else { $tangent_spiral_##ip + 25 } )

// Note: LEADING_TAPER_END evaluates to a chainage.

#define TRAILING_TAPER_START(ip) ( if($radius_##ip < 75)\
{ $spiral_tangent_##ip - 10 } else { $spiral_tangent_##ip - 25 } )

// Note: TRAILING_TAPER_START evaluates to a chainage.

#define TRAILING_TAPER_END(ip) ( if($radius_##ip < 75)\
{ $spiral_tangent_##ip + 50 } else { $spiral_tangent_##ip + 75 } )
```

```

// Note: TRAILING_TAPER_END evaluates to a chainage.
#define START_TAPER(ip) LEADING_TAPER_START(ip)\
    LEADING_TAPER_END(ip)

// Note: START_TAPER evaluates to two chainages:    chainge1  chainage2.
#define FIXED_TAPER(ip) LEADING_TAPER_END(ip)\
    TRAILING_TAPER_START(ip)

// Note: FIXED_TAPER evaluates to two chainages:    chainge1  chainage2.
#define END_TAPER(ip) TRAILING_TAPER_START(ip)\
    TRAILING_TAPER_END(ip)

// Note: TRAILING_TAPER evaluates to two chainages:    chainge1  chainage2.

#define SUPER(name, ip, x1, x2) \
\
    xfall name START_TAPER(ip) x1 x2 absolute \
    xfall name FIXED_TAPER(ip) x2 x2 absolute \
    xfall name END_TAPER(ip) x2 x1 absolute

```

With the above #defines, SUPER evaluates to three lines of xfall template modifiers which rotates cross-fall, keeps it constant and then counter-rotates the cross-fall about leading and trailing spirals for an HIP point.

For example,

```
SUPER(EB,2,-3,3)
```

would give expand to the following three lines of xfall commands for link **EB** which will rotate xfall from -3 to 3, hold it at 3 and then rotate it back from 3 to -3, all about the leading and trailing spirals for horizontal intersection point number two:

```

xfall EB begin_chainage_for_start_taper end_chainage_for_start_taper -3 3 absolute
xfall EB begin_chainage_for_fixed_taper end_chainage_for_fixed_taper_ch 3 3 absolute
xfall EB begin_chainage_for_end_taper end_chainage_for_end_taper 3 -3 absolute

```

The above definitions of SUPER could be placed in a file, say

```
f:\12d\12dmodel\library\super_mtf.def
```

and then simply included into a mtf file using the a #include:

```
#include f:\12d\12dmodel\library\super_mtf.def
```

Examples of Substitutions in the Many Templates File

The following example shows how #defines can be used to easily apply super-elevation according to rules involving leading and trailing spirals.

The definition of SUPER is given in the file, f:\12d\12dmodel\library\super_mtf.def, which is simply included in the mtf file using a #include.

```
// -----
// include the file containing the definition of SUPER
// -----

#include "f:\12d\12dmodel\library\super_mtf.def"

// -----
// apply templates left and right and then modifier them
// -----

left_side = {
    -999999 std
    999999
}

right_side = {
    -999999 std
    999999
}

specials = {
}

hinge_modifier = {
}

left_side_modifier = {
// linearly widen the link EB by 12 metres and bring it back
// in again.

width EB ($tangent_spiral_2 - 50) ($tangent_spiral_2 + 50) 0 12
width EB ($tangent_spiral_2 + 50) ($spiral_tangent_7 - 50) 12 12
width EB ($spiral_tangent_7 - 50) ($spiral_tangent_7 + 50) 12 0

// define superelevation

    SUPER(EB,2,-3,3)
    SUPER(EB,4,-3,3)
    SUPER(EB,5,-3,3)
    SUPER(EB,6,-3,3)
}

right_side_modifier = {

    SUPER(EB,3,-3,3)
    SUPER(EB,7,-3,3)
}

stripping = {
}

//boxing_file = "yourfile.bf"
```

```
left_boxing = {  
}  
right_boxing = {  
}  
string_modifiers = {  
}  
//section_width = 10000.0
```

Full Definition of Boxing

Defining and applying boxing is similar to applying templates.

First there needs to be a file **defining the boxing** across a section (the boxing definition file, ending in .bf) and then there are commands for **applying the boxing definitions** along the reference string.

The boxing can be applied using any of the commands

- (a) apply many
- (b) boxing
- (c) boxing many.

For the **apply many** command, the boxing is defined in terms of the string names from the applied templates (**after** the LHS and RHS prefix adjustments).

For both the **boxing** and **boxing many** commands, the boxing is applied to a model of 4d strings representing x-sections across the whole road.

These labelled 4d strings can be generated by either

- (a) cuts through strings
- (b) apply many with the flag "sections as 4d" set

and the **text** at each point in the 4d string (point text) is the **name of the string** that the section cuts through at that point.

For the boxing to work properly, the string names created by the apply many, or the point names across the 4d string, must be unique for that section.

Note - in an apply many, the LHS, RHS prefix flag can be used to give strings different names even when the same template is used on the left and the right side.

Boxing sections are generated by the apply many, boxing and boxing commands but boxing strings are only generated by the apply many command. For the other cases, the option Strings=>Utilities=>Strings from sections can be used to create the boxing strings from the boxing sections.

Boxing Definitions

Boxing is defined by a series of commands going from **left to right** across the points of a cross section. (Cross sections are generated as 4d strings or super strings by options such as **apply** and **cuts**).

The definitions of boxing cross sections are set up in a file ending in .bf (called the boxing file) and any number of boxing definitions can be placed in the boxing file as long as each boxing definition is given a unique name.

The boxing file can be created with an editor or interactively from within 4d.

The interactive definition will now be described and the definition of the actual commands written to the file will be given later.

The boxing commands apply from the offset specified at the beginning of that command (**start offset** for the command) to the start offset of the **next** boxing command (like chainages and templates in the mtf). Hence the **end offset** for a command is the start offset of the following command in the file.

The **offsets** can be **fixed** values or can be specified **relative** to a point name on the super string or 4d string representing the x-section. One restriction is that all the points mentioned in a boxing definition, must be present in each x-section the boxing definition is applied to.

The terminology used to specify an offset relative to a point name is "relative point offset" and is defined to be the offset at a given named point on the cross section, plus a given offset value.

That is

take the **offset at** the 4d point or super string point called "**point name**" and add "**offset value**" to it (the offset value can be positive or negative).

If the "point name" is blank, then the "offset value" is taken to be the *actual* offset on the super string.

Hence the *offset* can be specified as either an actual **offset value** or given **relative to the name of a point** on the super string (**relative offset**). For convenience, the offset will be denoted by **relative point offset**.

The major advantage of defining boxing in terms of point names is that whenever the points are modified using template modifiers, the boxing across the section is also automatically modified.

A boxing definition may be used in either a `left_boxing` or `right_boxing` mtf command (see the section, creating boxing), however unlike the case for templates, the boxing definition is applied to the point names going from left to right regardless of whether the boxing definition is used on the left or the right.

In practice, the definitions for left and right boxing are usually different because of the necessity of having unique point names across the entire cross section.

Vertical Walls

If a boxing definition creates two different height values at the one offset (i.e. a wall), then extra offset points are automatically inserted into the boxing x-section (at 0.1 mm from the previous point) so that no points are on top of each other.

So in effect a vertical wall is created but since no points are created that are directly above each other, the data can be triangulated.

Please continue to the next section "Edit Boxing File" .

Edit Boxing File

edit_boxing_definitions

The option Design =>Boxing =>Create creates a boxing definition file and then brings up the **Edit Boxing Definitions** panel to create the actual boxing definitions (rules) to save in the boxing definitions file.

Similarly selecting a boxing file from the walk-right list of Design =>Boxing =>Edit also brings up the **Edit Boxing Definitions** panel to create/edit boxing definitions from the selected definitions file.

The **Edit Boxing Definitions** panel is

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Boxing definition	input		boxing definitions in file

name of the boxing definition (in the current boxing file) to create or edit.

Create button

*create a boxing definition with name given by the boxing definition panel field
If the boxing definition given in the boxing definition field **does not exist**, then the **boxing rules panel** is placed on the screen and is used to created the new boxing definitions for the boxing file.
If the boxing definition already exists, then nothing will happen on selecting **create**.*

Edit button

*edit an existing boxing definition with name given by the boxing definition panel field
If the boxing definition given in the boxing definition field **exists**, then the **boxing rules panel** is placed on the screen and is used to edit the existing boxing definitions for the boxing file.
If the boxing definition does not exist exists, then nothing will happen on selecting **edit**.*

Delete button

*delete an existing boxing definition with name given by the boxing definition panel field
A **yes-no** panel confirms the deletion.*

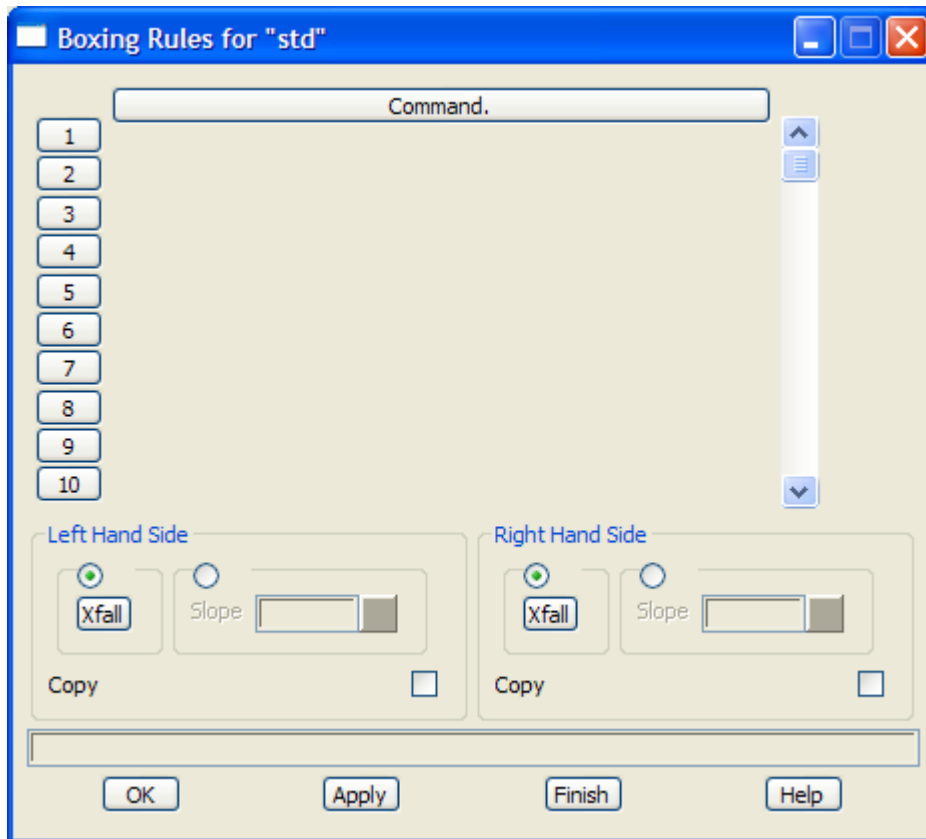

Save file button

save the boxing file with the boxing definitions to disk.

For more information on how Boxing works in 12d Model, please go to the section "Boxing".

boxing_rules_for

Selecting the **Create** or **Edit** button brings up the **Boxing Rules** panel which is used to build up the boxing definition from the rules described in the following sections.

The **Boxing Rules** panel consists of a scrolling command field, LHS and RHS xfall buttons, LHS and RHS slope fields, LHS and RHS copy tick box boxes and an **OK** or **Apply** button to record the results. The Commands and the LHS xfall and RHS xfall options will be described separately

The other fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
-------------------	------	----------	--------

Commands	Scrolling table		
-----------------	-----------------	--	--

commands for defining the boxing. The commands will be described in the next section.

Left Hand Side

LHS Xfall	button
------------------	--------

brings up the LHS Xfall panel which is described in the later section "LHS Xfall" .

or

LHS slope	input
------------------	-------

If non-zero, a batter with the given slope is applied to the left at the beginning of the boxing and goes until it intersects the design section. The intersection point is added as the first point in the boxing. If no intersection is made, nothing is added to the boxing. A positive slope is up and negative down.

LHS copy	tick box
-----------------	----------

if tick, then the design section from the beginning of the design section to the beginning of the boxing section is copied to the beginning of the boxing section. Hence the LHS copy flag is used to begin the boxing section with the start of the design section (a full width left side boxing section).

If not tick, nothing is done

Right Hand Side

RHS Xfall	button
------------------	--------

brings up the *RHS Xfall* panel which is described in the later section “*RHS Xfall*” .

or

RHS slope input

if non-zero, a batter with the given slope is applied to the right at the right end of the boxing and goes until it intersects the design section. The intersection point is used as the next point in the boxing. If no intersection is made, nothing is added to the boxing. A positive slope is up and negative down.

RHS copy tick box

*if tick, then the design section from the from the last boxing point to the last point on the design section is copied to the end of the boxing section. Hence the *RHS copy* flag is used to continue the boxing section from the intersection point with the design section to the end of the design section (a full width right side boxing section).*

If not tick, nothing is done

OK/Apply button

OK stores the values in the fields and removes the panel.

Apply stores the values and leaves the panel on the screen.

Notes

1. The **Left xfall** command **takes precedence over** the **Left slope** command. That is, if both commands exist then only the *Left xfall* command is used. Both *Left xfall* and *Left slope* can be missing. Similarly for the *Right xfall* and *Right slope* commands.
2. When a boxing definition is applied on the left side in the mtf, any *Right xfall*, *Right slope* or *Right copy* is ignored. Similarly, when a boxing definition is applied on the right side in a mtf, any *Left xfall*, *Left slope* or *Left copy* is ignored.

Hence a boxing definition can have all of *Left xfall*, *Left slope*, *Left copy*, *Right xfall*, *Right slope* and *Right copy* but which set is used depends on whether the boxing definition is used on the left or the right.

When the **Boxing** panel is used to create the boxing it is applied to a complete section at once so only one boxing definition is needed and all of the *Left xfall*, *Left slope*, *Left copy*, *Right xfall*, *Right slope* and *Right copy* commands are used.

For more information on how Boxing works in 12d Model, please go to the section “Boxing” .

[boxing_rule_create](#)

Commands for Boxing Rules Panel

If the command line is **empty**, clicking LB in the command line will bring up the Create menu which contains all the available boxing commands.

Selecting a menu item will bring up an associated panel which displays the information required for the modifier command.

When the panel is filled in and **OK** or **Apply** selected, the panel information is written out to the command line in the correct format for that modifier command.

If the command line is **not empty**, clicking LB in the command line will bring up the associated

panel for the modifier command in the command line.

The information in the panel can be changed and if **OK** or **Apply** is selected, the changed panel information is written out to the command line in the correct format for that modifier command.

Each of the panels created by selecting a command from the Create menu, will now be described. For reference purposes, the typed format of the command will be given for each panel although the typed format will not be described until later in the manual.

For documentation on the option/menus on the boxing *Create* menu:

- for *Copy*, go to the section "Copy" .
- X-fall* "Xfall - line through a point with a given crossfall" .
- X-fall 1* "Xfall 1 - line through a point with a crossfall taken from a point" .
- Line* "Line - line through two points" .
- End* "End" .

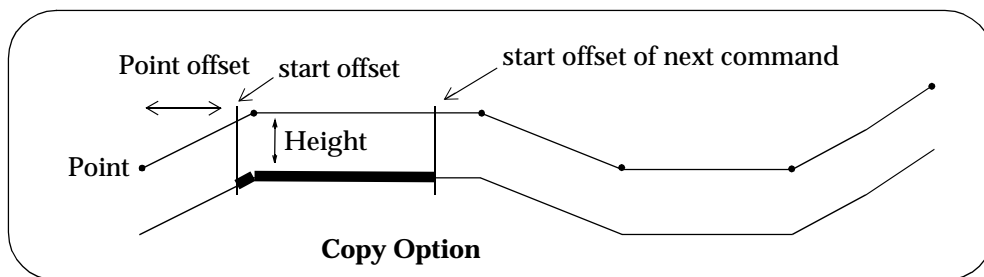

For more information on how Boxing works in 12d Model, please go to the section "Boxing" .

The text file definition of the boxing file is given in the section "Format of Boxing Definitions File"

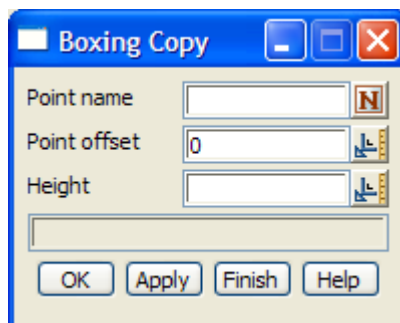

boxing_copy

Copy

The Copy command copies the links of the template (or parts of links) from the start offset (the offset of the given point plus the given **point offset** value), to the start offset of the *next* boxing command, keeping the present slope of each link but adjusting the height of each link by **height**. Height may be zero.

Selecting the copy option brings up the **boxing copy** panel

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
-------------------	------	----------	--------

- Point name** input
name of the point on the cross section (when adjusted by "point offset") to start the copy at.
- Point offset** input null
offset from the point given in the point name field.
- Height** input 0
Height to adjust the links of the template being copied.
- OK/Apply** button
*OK stores the values in the fields and removes the panel.
 Apply stores the values and leaves the panel on the screen.*

The typed formats of the **copy** and **copy with height adjustment** commands created by this panel are:

- point_name + point_offsetcopy
 and
 point_name + point_offset,copy, delta_height

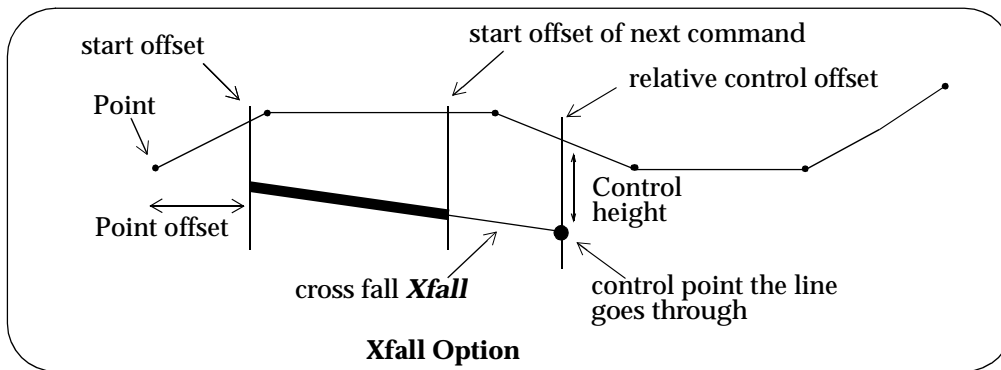

For more information on how Boxing works in 12d Model, please go to the section "Boxing" .

boxing_xfall

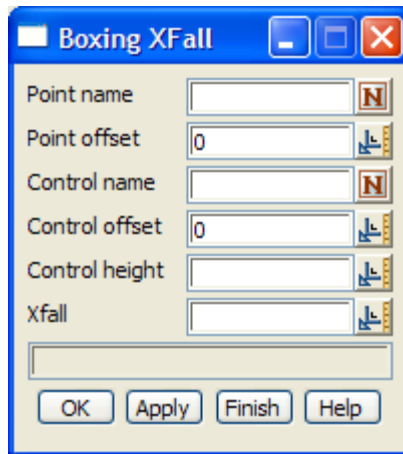

Xfall - line through a point with a given crossfall

The Xfall command creates a link from the start offset (the offset of the given point plus the given **Point offset**), to the start offset on the *next* boxing command, with a

- (a) user given cross fall (Xfall)
- (b) start height given by projecting to the start offset, the line with a given xfall and going through a given control point.

Selecting the xfall option brings up the **boxing xfall** panel

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
-------------------	------	----------	--------

Point name	input		
<i>name of the point on the cross section (when adjusted by point_offset) to start the line from.</i>			

Point offset	input	null	
<i>offset from the point given in the point name field.</i>			

Control name/offset/height	input		
<i>the control point that the line goes through has:</i>			
<i>offset of (control_name + control_offset)</i>			
<i>height of the above point on the template, + control_height</i>			

Xfall	input	0	
<i>crossfall of the line going through the control point.</i>			

OK/Apply	button		
<i>OK stores the values in the fields and removes the panel.</i>			
<i>Apply stores the values and leaves the panel on the screen.</i>			

The typed formats of the **xfall** commands created by this panel is:

point_name + point_offset, **xfall**, control_name + control_offset, control_height, xfall

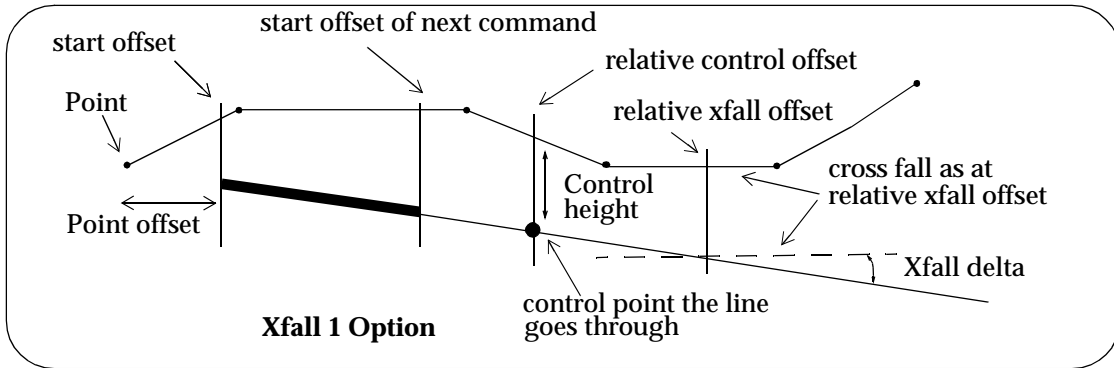

For more information on how Boxing works in 12d Model, please go to the section "Boxing" .

boxing_xfall_1

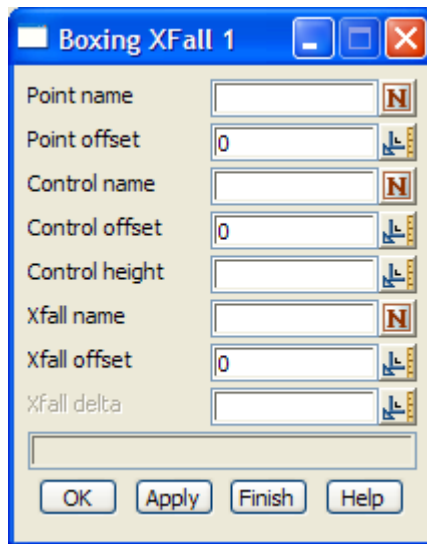

Xfall 1 - line through a point with a crossfall taken from a point

The Xfall 1 command creates a link from the start offset (the offset of the given point plus the given **Point offset**), to the start offset on the *next* boxing command, with a

- a cross fall which is the cross fall at a given point plus an additional cross fall (Xfall delta)
- start height given by projecting to the start offset, the line with the specified cross fall and going through a given control point.

Selecting the Xfall 1 option brings up the **Boxing Xfall 1** panel

The fields and buttons used in this panel have the following functions.

Field	Description	Type	Defaults	Pop-Up
Point name	name of the point on the cross section (when adjusted by point_offset) to start the line from.	input		
Point offset	offset from the point given in the point name field.	input	null	
Control name/offset/height	the control point that the line goes through has: offset of (control_name + control_offset) height of the above point on the template, + control_height	input		
Xfall name/offset	the crossfall is taken from the point on the template which has the offset of (control_name + control_offset)	input		
Xfall delta	adjust the crossfall at the xfall point by the xfall_delta.	input	0	
OK/Apply	OK stores the values in the fields and removes the panel.	button		

Apply stores the values and leaves the panel on the screen.

For more information on how Boxing works in 12d Model, please go to the section "Boxing".

The typed formats of the **xfall1** commands created by this panel is:

point_name + point_offset, **xfall1**, control_name + control_offset, control_height,
xfall_name + xfall_offset, xfall_delta

boxing_line

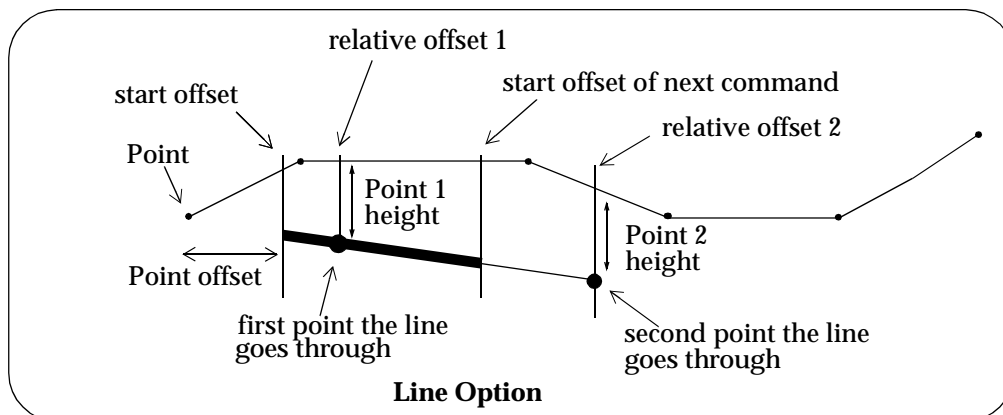

Line - line through two points

The Line command creates a line from the start offset (the offset of the given point plus the given **Point offset** value), to the start offset of the *next* boxing command, with a

- slope given by two points
- start height given by projecting to the start offset, the line through the two points.

The first point defining the line has the offset of "Point 1" plus the given "Point 1 offset" and a height given by the height of the design x-section at the offset adjusted by "Point 1 height".

The second point defining the line has the offset of "Point 2" plus the given "Point 2 offset" and a height given by the height of the design x-section at the offset adjusted by "Point 2 height".

Selecting the line option brings up the **boxing line** panel

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Point name <i>name of the point on the cross section (when adjusted by point_offset) to start the line from.</i>	input		
Point offset <i>offset from the point given in the point name field.</i>	input	null	
Point 1 name/offset/height <i>the first point that the line goes through has: offset of (point_1 + point_1_offset) height of the above point on the template + point_1_height</i>	input		
Point 2 name/offset/height <i>the second point that the line goes through has: offset of (point_2 + point_2_offset) height of the above point on the template + point_2_height</i>	input		
OK/Apply <i>OK stores the values in the fields and removes the panel. Apply stores the values and leaves the panel on the screen.</i>	button		

For more information on how Boxing works in 12d Model, please go to the section “Boxing” .

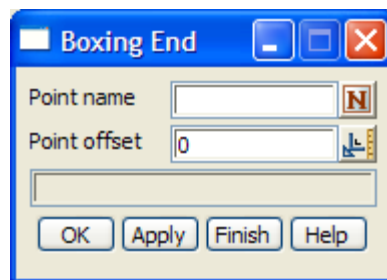

The typed format of the **line** commands created by this panel is (all on one line):

point_name + point_offset,**line**, point_1_name + point_1_offset,delta_height_1,
point_2_name + point_2_offset,delta_height_2

boxing_end

End

Selecting the end option brings up the **boxing end** panel

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Point name <i>name of the point on the cross section (when adjusted by point_offset) to finish the previous command at.</i>	input		
Point offset <i>offset from the point given in the point name field.</i>	input	null	
OK/Apply <i>OK stores the values in the fields and removes the panel. Apply stores the values and leaves the panel on the screen.</i>	button		

For more information on how Boxing works in 12d Model, please go to the section "Boxing".

The typed format of the **line** commands created by this panel is:

point_name + point_offset, **end**

boxing_lhs_xfall_for

LHS Xfall

The LHS Xfall command creates a line from the left hand end of the boxing already defined and then batters to the **left** at a specified cross fall until it intersects the design surface. The cross fall of the batter is defined as

(a) the cross fall at the *relative xfall offset* (the offset at the given point "Point name" plus "Xfall offset")

plus

(b) the additional cross fall value "Xfall delta"

If the design surface is not intersected, then no extra line is created.

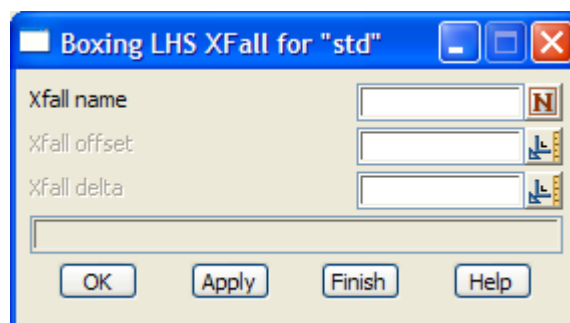

If *Copy* is toggle on in the *Left Hand Side* section of the **Boxing Rules** panel, then the part of the design section from beginning of the design section to the LHS cross fall intersection point is copied to the start of the boxing section.

In the left xfall command, the xfall is percent cross-fall and a positive xfall is up and negative down.

Note that the LHS xfall command creates a line at the **beginning** of the boxing. It is actually applied after all the other boxing commands have been run.

Selecting the LHS xfall button on the **boxing rules** panel brings up the **Boxing LHS Xfall** panel

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Xfall name/offset	input		
<i>the crossfall is taken from the point on the template which has the offset of Xfall_name + xfall_offset</i>			
Xfall delta	input	0	
<i>adjust the crossfall at the xfall point by the value Xfall_delta.</i>			
OK/Apply	button		
<i>OK stores the values in the fields and removes the panel.</i>			
<i>Apply stores the values and leaves the panel on the screen.</i>			

For more information on how Boxing works in 12d Model, please go to the section "Boxing" .

The typed formats of the **left_xfall** commands created by this panel is:

left_xfall, xfall_name + xfall_offset, xfall_delta

boxing_rhs_xfall_for

RHS Xfall

The RHS Xfall command creates a line beginning at the right hand end of the boxing already defined and then batters to the right at a specified cross fall until it intersects the design surface. The cross fall of the batter is defined as

(a) the cross fall at the *relative xfall offset* (the offset at the given point "Point name" plus "Xfall offset")

plus

(b) the additional cross fall value "Xfall delta"

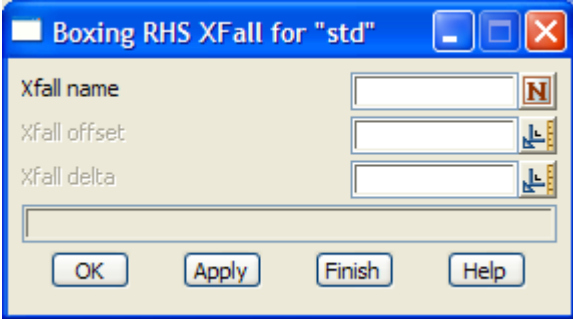

If the design surface is not intersected, then no extra line is created.

If *Copy* is toggle on in the *Right Hand Side* section of the **Boxing Rules** panel, then the part of the design section from the RHS cross fall intersection point to the last point of the design section is copied to the end of the boxing section.

In the right xfall command, the xfall is percent cross-fall and a positive xfall is up and negative down.

Selecting the RHS xfall button on the **boxing rules** panel brings up the **Boxing RHS Xfall** panel

The fields and buttons used in this panel have the following functions.

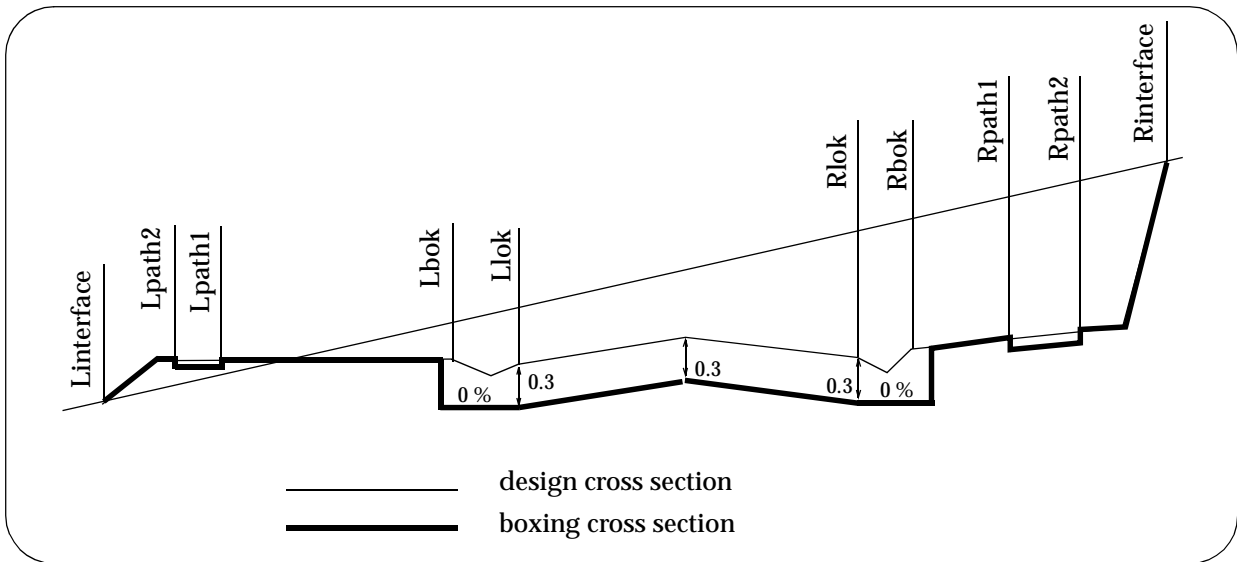

Field Description	Type	Defaults	Pop-Up
Xfall name/offset <i>the crossfall is taken from the point on the template which has the offset of Xfall_name + xfall_offset</i>	input		
Xfall delta <i>adjust the crossfall at the xfall point by the value Xfall_delta.</i>	input	0	
OK/Apply OK stores the values in the fields and removes the panel. Apply stores the values and leaves the panel on the screen.	button		

For more information on how Boxing works in 12d Model, please go to the section "Boxing" .

The typed formats of the **right_xfall** commands created by this panel is:

right_xfall, xfall_name + xfall_offset, xfall_delta

Boxing Definitions Examples

boxing "1" {

```

"Linterface",      copy                                // line 1
"Lpath2",         copy,      -0.075                // line 2
"Lpath1",         copy                                // line 3

    right_copy  1
}
boxing "full" { // a full width boxing - defines the entire boxing going from left to right
    "lkerb",    copy,    -0.6
    "rkerb",    end
    left_slope  5.0
    left_copy   1
    right_slope -5.0
    right_copy  1
}
```

Format of Boxing Definitions File

The interactive editor for creating the boxing definition file has been given in the previous sections “Edit Boxing File” .

This section will describe the layout of the text boxing file.

Boxing is defined by a series of commands going from **left to right** across the points of a cross section. (Cross sections are generated as 4d strings by options such as **apply** and **cuts**).

The definitions of boxing cross sections are set up in a file ending in **.bf** (called the boxing file) and any number of boxing definitions can be placed in the boxing file as long as each boxing definition is given a unique name.

In the boxing file, a boxing definition with name **boxing_name** is set out as

```
boxing    boxing_name {
                                boxing commands
}
```

The boxing commands apply from the offset specified at the beginning of that command (**start offset** for the command) to the start offset of the **next** command in the file (like chainages and templates in the apply many file). Hence the **end offset** for a command is the start offset of the following command in the file.

For example, in the sequence

```
offset1,    command1
offset2,    command2
```

command1 goes from offset1 (the start offset for command1) to offset2 (the end offset for command1).

The **offsets** can be **fixed** values or can be specified **relative** to a point name on the 4d string representing the x-section. One restriction is that all the points mentioned in a boxing definition, must be present in each x-section the boxing definition is applied to.

The notation used to specify an actual offset, or offset relative to a point name is

```
offset_value
or      "point_name"
or      "point_name" +/- offset_value
```

and means in the first case

take the specified **offset** value (offset_value can be positive or negative).

and for the other two relative cases

take the **offset** at the string or 4d point called **point_name** and add **offset_value** to it (offset_value can be positive or negative).

Hence the offset can be specified as either a value or given **relative to point_name** (relative

offset). For convenience, the offset will be denoted by **rel_off**.

The major advantage of defining boxing in terms of point names is that whenever the points are modified using template modifiers, the boxing across the section is also automatically modified.

Since the offset part of a command can consist of text plus or minus a number, commas are used to separate each field of the command.

A boxing definition may be used in either a `left_boxing` or `right_boxing` mtf command (see the section, creating boxing), however unlike the case for templates, the boxing definition is applied to the point names going from left to right regardless of whether the boxing definition is used on the left or the right.

In practice, the definitions for left and right boxing are usually different because of the necessity of having unique point names across the entire cross section.

The commands in the boxing definition are

Copy

`rel_off, copy`

This copies the links (or parts of links) from the start offset **rel_off** to the offset on the next line, keeping the present crossfall and height of each link

Copy with Height Adjustment

`rel_off, copy, delta_height`

This copies the links (or parts of links) from the start offset **rel_off** to the offset on the next line, keeping the present slope of each link but adjusting the height of each link by **delta_height**.

Line Through Two Given Points

rel_off, **line**, rel_off_1, delta_height_1, rel_off_2, delta_height_2

This creates a link from the start offset **rel_off** to the offset on the next line, with a

- (a) slope given by two points
- (b) start height given by projecting to the start offset, the line through the two points.

The first point defining the line has an offset **rel_off_1** and a height given by the height of the design x-section at offset **rel_off_1** adjusted by **delta_height_1**.

The second point defining the line has an offset **rel_off_2** and a height given by the height of the design x-section at offset **rel_off_2** adjusted by **delta_height_2**.

Xfall - Line Through a Given Point with a Given Crossfall

rel_off, **xfall**, rel_off_1, delta_height_1, xfall_value

This creates a link from the start offset to the offset on the next line, with a

- (a) user given xfall
- (b) start height given by projecting to the start offset, the line with a given xfall and going through a given point.

The point defining the line has an offset **rel_off_1** and a height given by the height of the design x-section at offset **rel_off_1** adjusted by **delta_height_1**.

The crossfall of the line is given by **xfall_value**

Xfall1 - Line Through a Given Point with Crossfall Taken from a Point

rel_off, **xfall1**, rel_off_1, delta_height_1, rel_off_2, delta_xfall

This creates a link from the start offset **rel_off** to the offset on the next line, with a

(a) xfall which is the xfall at a given offset plus an addition given xfall

and

(b) start height given by projecting to the start offset, the line with the given xfall and going through a given point.

The point defining the line has offset **rel_off_1** and a height given by the height of the design x-section at offset **rel_off_1** adjusted by **delta_height_1**

The xfall of the line is **delta_xfall** added to the xfall on the design x-section at the offset **rel_off_2**

rel_off, **xfall1**, rel_off_1, delta_height_1, rel_off_2, delta_xfall
next_off, ...

End

rel_off, **end**

This command is used to give an end offset for any of the above commands when no command follows to use for the end offset. That is, the offset **rel_off** is used as the **end offset** for the **previous command**.

end doesn't begin another command and none of the above commands can follow an **end** command.

All of the above boxing commands are known as **standard** commands. Hence the **end** command is the **last** standard command.

Right_Xfall - Batter off Right End of Boxing with Crossfall Taken from a Point

The **right_xfall** command has two versions - providing a fixed cross fall or using the crossfall from part of the design x-section.

right_xfall rel_off, delta_xfall

right_xfall xfall_value

For the first case, the **right_xfall** command batters off the right end of the boxing using the xfall from the design section at a given offset *rel_off* plus an additional given xfall *delta_xfall*, until the design section is intersected. The intersection point is used as the next point in the boxing.

Hence the xfall of the batter is **delta_xfall** added to the xfall on the design x-section at the offset **rel_off**

For the second case, the **right_xfall** command batters off to the right end of the boxing at the given xfall **xfall_value** until the design section is intersected. The intersection point is used as the next point in the boxing.

In the **right_xfall** command, the xfall is percent cross-fall and a positive xfall is up and negative down.

Right_slope - Batter Off the Right End of Boxing with a Given Crossfall

right_slope slope_value

The **right_slope** commands batter off to the right end of the boxing at the given slope **slope_value** until the design section is intersected. The intersection point is used as the next point in the boxing. In this command, a positive slope is up and negative down.

Right_copy - Copy from the Last Boxing Point to the end of Design Section

right_copy value

If value is non-zero, the **right_copy** command copies from the last boxing point to the last point on the design section. Hence the **right_copy** command is used to continue the boxing section from the intersection point with the design section to the end of the design section (a full width boxing section).

Note

The **right_xfall** command **takes precedence over** the **right_slope** command. That is, if both commands exist then only the **right_xfall** command is used.

Left_xfall

left_xfall rel_off, delta_xfall
left_xfall xfall_value

The `left_xfall` is identical to the `right_xfall` command except that it is applied at the beginning of the boxing definition and batters off to the left rather than to the right.

In the `left_xfall` command, the `xfall` is percent cross-fall and a positive `xfall` is up and negative down.

Left_slope

left_slope slope_value

The `left_slope` is identical to the `right_slope` command except that it is applied at the beginning of the boxing definition and batters off to the left rather than to the right. In this command, a positive slope is up and negative down.

The `left_slope` and `left_copy` are identical to the `right_slope` and `right_copy` except that they are applied at the beginning of the boxing definition and batter off and copy to the left rather than to the right. In this command, a positive slope is up and negative down.

The `left_copy` command must come before the `left_slope` command but they both come after all of the standard commands.

Note

The `left_xfall` command **takes precedence over the `left_slope`** command. That is, if both commands exist then only the `left_xfall` command is used.

Left_copy

left_copy value

The `left_copy` is identical to the `right_copy` except that it is applied at the beginning of the boxing definition and copies to the left rather than to the right.

If *value* is non-zero, the `left_copy` command copies from the last boxing point to the last point on the design section. Hence the `left_copy` command is used to continue the boxing section from the first boxing point to the start of the design section (a full width boxing section).

Note

The `left_xfall`, `left_slope`, `left_copy`, `right_xfall`, `right_slope` and `right_copy` commands should come after all of the standard commands.

When a boxing definition is applied on the left side, any `right_xfall`, `right_slope` or `right_copy` is ignored. Similarly, when a boxing definition is applied on the right side, any `left_xfall`, `left_slope` or `left_copy` is ignored.

Hence a boxing definition can have a `left_xfall`, `left_slope`, `left_copy` and a `right_xfall`, `right_slope`, `right_copy` but which set is used depends on whether the boxing definition is used on the left or the right.

When the **boxing** panel is used to create the boxing, only one boxing definition is needed and all of the `right_xfall`, `right_slope`, `right_copy`, `left_xfall`, `left_slope` and `left_copy` commands are used.

Vertical Walls

If a boxing definition creates two different height values at the one offset (i.e. a wall), then extra offset points are automatically inserted into the boxing x-section (at 0.1 mm from the previous point) so that no points are on top of each other.

So in effect a vertical wall is created but since no points are created that are directly above each other, the data can be triangulated.

Boxing Definitions Examples

boxing "1" {

```

"Linterface",      copy                               // line 1
"Lpath2",         copy,      -0.075           // line 2
"Lpath1",         copy                               // line 3
"Lbok" - 0.15,    xfall,      "Llok",      -0.3,      0       // line 4
"Llok",           copy,      -0.3            // line 5
"Rlok",           xfall,      "Rlok",      -0.3,      0       // line 6
"Rbok" + 0.15,    copy                               // line 7
"Rpath1",         copy,      -0.095          // line 8
"Rpath2",         copy                               // line 9
"Rinterface",     end                               // line 10
    }
```

Description

Line 1 copy from "Linterface" to "Lpath2"
 Line 2 copy and drop by 0.075 from "Lpath 2" to "Lpath 1"
 Line 3 copy from "Lpath1" to 0.15 before "Lbok"
 Line 4 go from 0.15 before "Lbok" to "Llok" at depth 0.3 below "Llok", with cross fall 0
 Line 5 copy and drop by 0.3 from "Llok" to "Rlok"
 Line 6 go from "Rlok" to 0.15 past "Rbok" at depth 0.3 below "Rlok", with cross fall 0
 Line 7 copy from 0.15 past "Rbok" to "Rpath1"
 Line 8 copy and drop by 0.095 from "Rpath1" to "Rpath2"
 Line 9 copy from "Rpath2" to "Rinterface"

```

boxing "left narrow" {           // boxing defined from just before lkerb to m001
    "lkerb" - 0.7 ,             copy
    "m001" - 1.0,              copy ,   -0.6
    "m001",                     end
}

boxing "left" { // boxing defined from the left start of the section to m001 (the centreline say)
    "lkerb",    copy,          -0.6
    "m001",     end
    left_slope  5.0
    left_copy   1
}

boxing "right" { // boxing defined from m001 to the far right of the section
    "m001",    copy,          0.6
    "rkerb",   end
    right_slope 5.0
    right_copy 1
}

boxing "full" { // a full width boxing - defines the entire boxing going from left to right
    "lkerb",    copy,          -0.6
    "rkerb",    end
    left_slope  5.0
    left_copy   1
    right_slope -5.0
    right_copy 1
}

```

Please continue to the next section "Applying Boxing" .

Applying Boxing

There are four options to apply boxing rules and hence create boxing strings and sections.

(a) Templates => Apply => Apply many

(b) Templates => Boxing => Boxing

with panel fields

model to box

boxing file

start chainage

end chainage

model for boxing

model of design x-sections

file containing one boxing definition

i.e. model for created boxing x-sections

(c) Templates => Boxing => Boxing many

with panel fields

model to box

templates file

boxing file

model for boxing

model of design x-sections

many template file, *.mtf

file of boxing definitions, *.bf

i.e. model for created boxing x-sections

(d) Templates => Boxing => Boxing many (function)

The panels for these options have been described in an earlier chapter.

When using the **boxing** option **Boxing**, only one boxing definition is used from the boxing definitions file given **boxing file** panel field.

For the **Apply many**, **Boxing many** and **Boxing many (function)** options, the application of the boxing definitions is given in the many templates file (*.mtf) and is similar in format to applying templates (except interpolating between boxing is not allowed).

In the *mtf* (**many templates file**), for the **Apply many**, there can be up to with layers of boxing and each layer is defined in two parts - the left boxing and the right boxing. If both left and right boxing are both defined at a section, then the last point of the left boxing is automatically connected to the first point of the right boxing.

Warning - the left boxing must end before the right boxing begins. If there is an overlap, the right boxing will be pushed to the end of the left boxing.

Apart from a key word specifying whether the following part of the definition is for the left or the right, the set out for the left boxing is identical to the right boxing. Hence only the left boxing will be described in detail.

The left boxing definition begins with the key words

left_boxing =

A list of chainages (in ascending order, one per line) with corresponding boxing names then follows. The list of chainages and boxing is enclosed in curly braces { }.

The chainage-boxing lists are assembled as follows

(a) to represent a boxing starting at a given chainage, the chainage value followed by the boxing name is given. The chainage and boxing name are separated by one or more spaces. For example, the boxing **left** starting at chainage 150 is represented by

150 left

The boxing is assumed to apply until the chainage given on the next line of the left_boxing definition.

- (b) if no boxing exists from a chainage, simply include the chainage with no boxing name following it. For example, if there is no boxing from chainage 250, this is represented by

```
250
```

The non-existence of boxing is assumed until the chainage given on the next line of the `left_side` definition.

If the boxing is to go to the end of the reference string, add a line with a chainage greater than or equal to the end chainage. For example

```
150      left
9999
```

When using the **apply many** option, the name of the boxing definitions file is given by a **boxing_file** command in the many templates file.

```
boxing_file =      boxing_definitions_file
```

When using the **boxing many** option, if a file name is given in the **boxing file** panel field, it is used for the boxing definitions file, otherwise the `boxing_file` command in the many templates file is used.

Note - if the boxing name includes spaces, then the name must be enclosed in quotes ". For example, "left 1".

An Applying Boxing Example

```
boxing_file = "boxing_for_client.bf"
left_boxing = {
                -999      left
                30
                70        "left narrow"
                110.5     left
                999
            }
right_boxing = {
                -999      right
                30
                70        "right narrow"
                110.5     right
                999
            }
```

Warning - no interpolation or modifiers exist for boxing.

Please continue to the next section "Boxing and Volumes".

Boxing and Volumes

For the **Apply many** option, the cut and fill areas and volumes are calculated from the bottom of the boxing to the stripped surface.

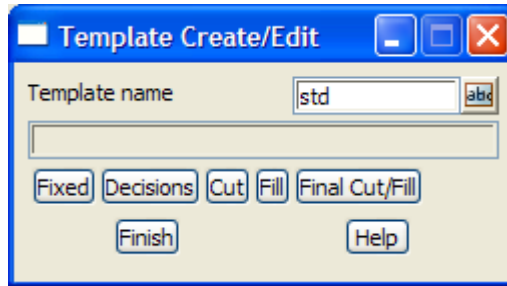

Full Definition of Template Decisions

decisions_template

12d Model supports templates with an unlimited number of fixed links, followed by either

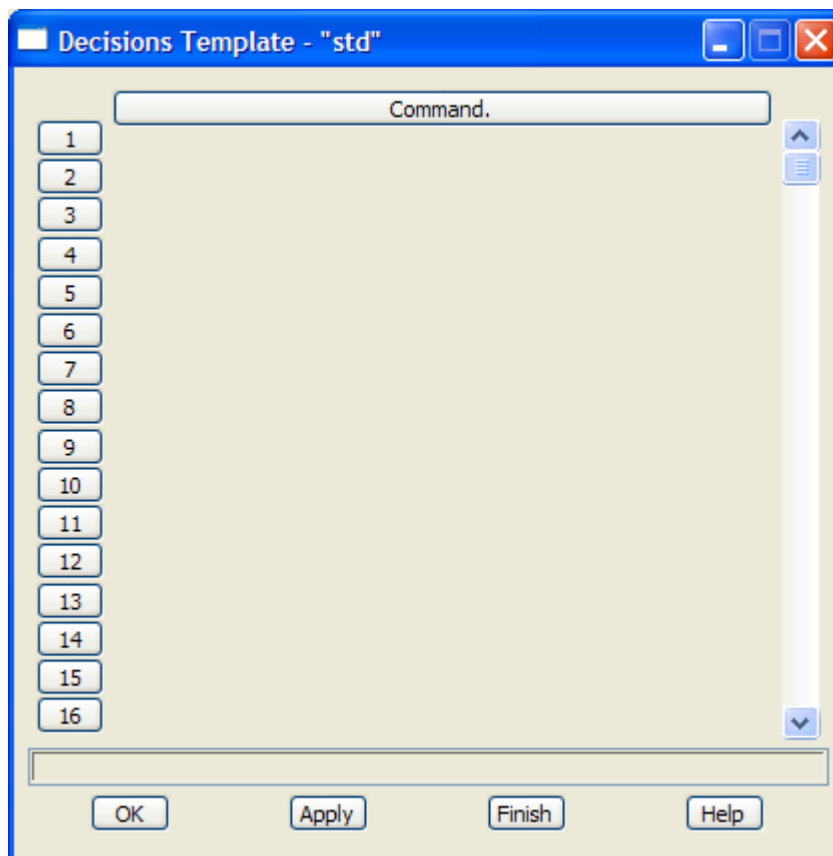

- (a) a decisions table
- or
- (b) an unlimited number of cut and fill links and a final cut/fill slope to be applied at the end of the last template link.

Templates are created and edited using the Templates=>Create/edit option which brings up the **Template Create/Edit** panel.

The description of the fields and the buttons **Fixed**, **Cut**, **Fill**, **Final Cut/Fill** in this panel were given in the chapter "Design".

The **Decisions** button and its associated panel, **Decisions Template**, which is created when the **Decisions** button is selected, will now be described.

The **Decisions Template** panel consists of scrolling command fields and a **OK** or **Apply** button to record the results.

The **width** of the command area in the **Decisions Template** panel is controlled by the environment variable `DEFAULT_TABLE_WIDTH_4D`.

The **commands** in the decision template form a simple language where the commands are processed sequentially unless control is passed to a labelled line from where sequential processing continues, or the processing is terminated by an **end** command.

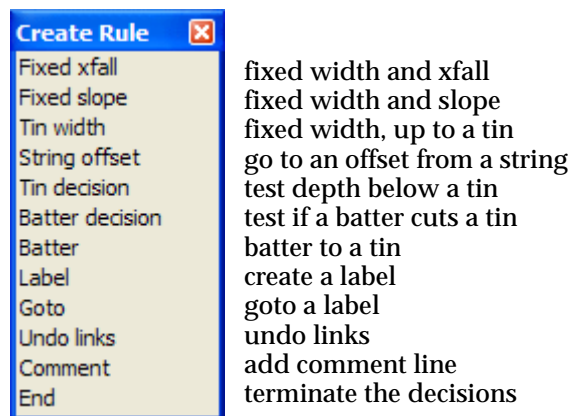

The decision template commands can:

- (a) create a fixed link - **fixed xfall** and **fixed slope**
- (b) create a link of fixed width but with a slope automatically selected so that the link reaches a given tin in the width - **tin width**
- (c) create a link that goes within an offset of a given string **string offset**
- (d) test for being between two depths below a tin, and transfer control if true - **tin decision**
- (e) test that a link would get within a given depth from a tin at a given offset, and transfer control if true - **batter decision**
- (f) create a link of set slope that batters to a depth below a tin at a given offset - **batter**
- (g) create a label which can have processing passed to - **label**
- (h) transfer processing to a given label - **goto**
- (i) end the processing of commands - **end**

decision_create_rule

The template decision commands can be typed into an text (ascii) file defining a template (template file .tpl), or can be created and edited through panels.

If the command line is **empty**, clicking LB in the command line will bring up the Create Rule menu which contains all the available decisions commands.

Selecting a menu item will bring up an associated panel which displays the information required for the decisions command.

When the panel is filled in and **OK** or **Apply** selected, the panel information is written out to the command line in the correct format for that template decision command.

If the command line is **not empty**, clicking LB in the command line will bring up the associated panel for the template decisions command in the command line.

The information in the panel can be modified and if **OK** or **Apply** is selected, the modified panel information is written out to the command line in the correct format for that template decisions command.

If the template is written out using `File I/O=>Templates output` or `Templates=>Utilities=>Output`, the template decisions will be written out as they are displayed in the command fields.

Any of the commands in the templates file can be edited and the file read back into 12d Model.

Each of the template decision commands will now be described and the associated panels created by selecting the command from the Create Rule menu.

The format of the decision commands that are written to the panel are given, as are the typed form of the command which is used in the templates file.

For examples of a using decisions, please go to the section “Decisions Examples” .

For documentation on the option/menus on the Create Rule menu:

for	<i>Fixed xfall</i>	go to the section “Fixed Xfall”
	<i>Fixed slope</i>	“Fixed Slope”
	<i>Tin width</i>	“Tin Width”
	<i>String offset</i>	“String Offset”
	<i>Tin decision</i>	“Tin Decision”
	<i>Batter decision</i>	“Batter Decision”
	<i>Batter</i>	“Batter”
	<i>Label</i>	“Label”
	<i>Goto</i>	“Goto”
	<i>Undo links</i>	“Undo”
	<i>Comment</i>	“Comment” .
	<i>End</i>	“End”

Please continue to the next section “Fixed Xfall” .

Fixed Xfall

decision_fixed_xfall

Selecting Fixed xfall brings up the **Fixed Xfall** panel which is used to constructed the command for a fixed link. The fixed link is defined by specifying values for two of the three fields width, height and x-fall.

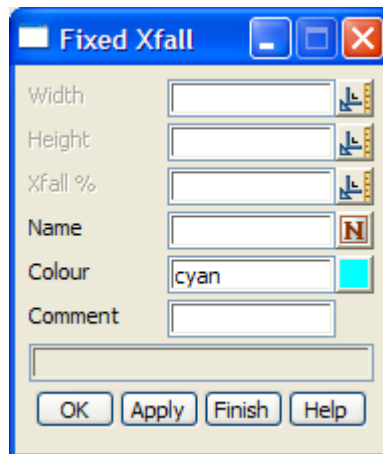

The format of the Fixed Xfall command in the panel is

Fixed Xfall Width *value* Height *value* XFall *value* Name *text* Colour *colour* // *comment*
 where only two of the three commands Width, Height and Xfall are used.

The format of the command typed into the template file is

Fixed_Xfall *width_value* *height_value* *xfall_value* *name* *colour* // **comment**
 where one of *width_value*, *height_value* or *xfall_value* is the key word *unknown*.

The panel brought up when Fixed xfall is selected from the Create Rule menu is:

The fields and buttons used in this panel have the following functions.

Field Description	Type	Default	Pop-Up
Width <i>the width for the link.</i>	input		
Height <i>the height for the link.</i>	input		
Xfall %	input		

the x-fall, in percent cross-fall, of the link. Positive is up and negative down.

Name input

the name to be used for the created point and string.

Colour input cyan available colours

the colour to be used for the created string

Comment input

user comment - for information purposes only

OK/Apply button

***OK** stores the values in the fields and removes the panel.*

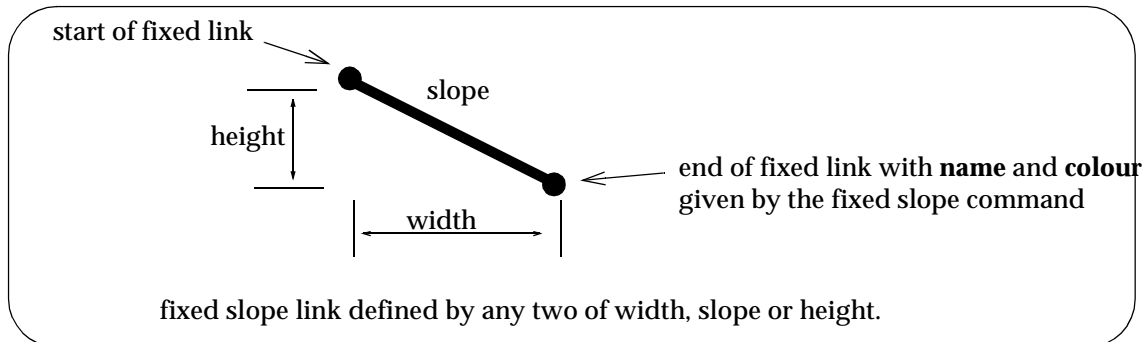

***Apply** stores the values and leaves the panel on the screen.*

Please continue to the next section "Fixed Slope" .

Fixed Slope

decision_fixed_slope

Selecting Fixed slope brings up the **Fixed Slope** panel which is used to constructed a fixed link. The fixed link is defined by specifying values for two of the three fields width, height and slope.

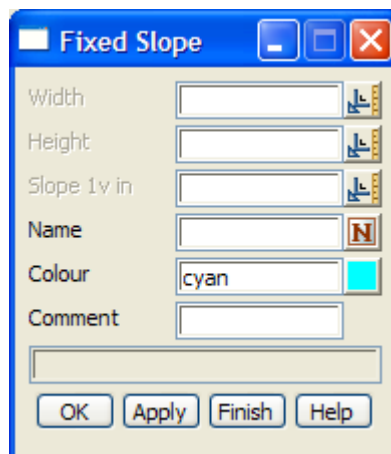

The format of the Fixed Slope command in the panel is

Fixed Slope Width *value* Height *value* Slope *value* Name *text* Colour *colour* // *comment*
 where only two of the three commands Width, Height and Slope are used.

The format of the command typed into the template file is

Fixed_Slope *width_value* *height_value* *slope_value* *name* *colour* // *comment*
 where one of *width_value*, *height_value* or *slope_value* is the key word *unknown*

The panel brought up when Fixed slope is selected from the Create Rule menu is:

The fields and buttons used in this panel have the following functions.

Field Description	Type	Default	Pop-Up
Width <i>the width for the link.</i>	input		
Height <i>the height for the link.</i>	input		
Slope 1v in	input		

the slope, in 1v in, of the link. Positive is up and negative down.

Name input

the name to be used for the created point and string.

Colour input cyan available colours

the colour to be used for the created string

Comment input

user comment - for information purposes only

OK/Apply button

OK stores the values in the fields and removes the panel.

Apply stores the values and leaves the panel on the screen.

Please continue to the next section "Tin Width" .

Tin Width

decision_tin_width

Selecting Tin width brings up the **Tin Width** panel which is used to construct a link which has a given width and stops at the depth strip below the tin. Control then passes to the next line of the table.

strip can be positive (end point is below the tin) or negative (end point is above the tin).

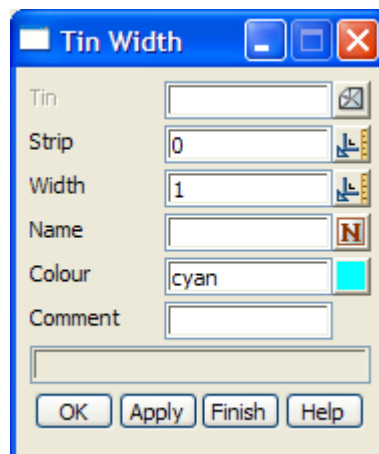

The format of the Tin Width command in the panel is

Tin Width *tin_name* Strip *value* Width *value* Name *text* Colour *colour* // *comment*

The format of the command typed into the template file is

Tin_Width *tin_name* *strip_value* *width_value* *name* *colour* // *comment*

The panel brought up when Tin width is selected from the Create Rule menu is:

The fields and buttons used in this panel have the following functions.

Field	Description	Type	Default	Pop-Up
Tin	<i>tin to batter to.</i>	input		available tins
Strip	<i>distance below the tin to stop at (strip depth). strip can be positive (point is below the tin) or negative (point is above the tin).</i>	input	0	
Width		input	1	

width of the link

Name input

the name to be used for the created point and string.

Colour input cyan available colours

the colour to be used for the created string

Comment input

user comment - for information purposes only

OK/Apply button

OK stores the values in the fields and removes the panel.

Apply stores the values and leaves the panel on the screen.

Please continue to the next section "String Offset" .

String Offset

decision_string_offset

Selecting String offset brings up the **String Offset** panel which is used to construct a link which goes to a given offset from string and stops at the depth strip below the string. Control then passes to the next line of the table.

offset and string can be positive or negative.

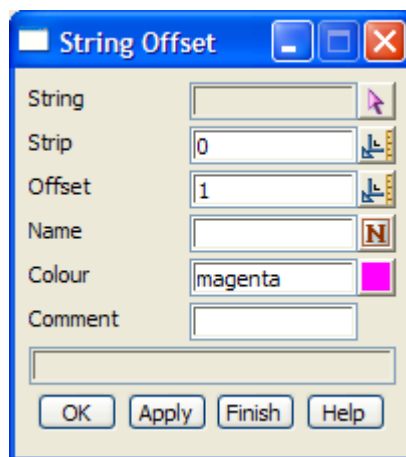

The format of the String Offset command in the panel is

String Offset *string_name* Strip *value* Offset *value* Name *text* Colour *colour* // *comment*

The format of the command typed into the template file is

String_Offset *string_name* *strip_value* *offset_value* *name* *colour* // *comment*

The panel brought up when String offset is selected from the Create Rule menu is:

The fields and buttons used in this panel have the following functions.

Field Description	Type	Default	Pop-Up
String <i>string to batter to.</i>	string select		
Strip <i>distance below the string to stop at.</i>	input	0	
Offset <i>offset from the string to stop at.</i>	input	1	

Name input
the name to be used for the created point and string.

Colour input cyan available colours
the colour to be used for the created string

Comment input
user comment - for information purposes only

OK/Apply button
OK stores the values in the fields and removes the panel.
Apply stores the values and leaves the panel on the screen.

Please continue to the next section “Tin Decision” .

Tin Decision

decision_tin_decision

Selecting Tin decision brings up the **Tin Decision** panel which tests to see if the depth from the end of the previous link, offset by the amount given in the offset field, is between the two values given in the minimum depth and maximum depth fields. If the depth is between the values, then control is transferred to the line with the label given by the goto field. Otherwise, control passes to the next line of the table.

offset, minimum and maximum depth can be positive or negative.

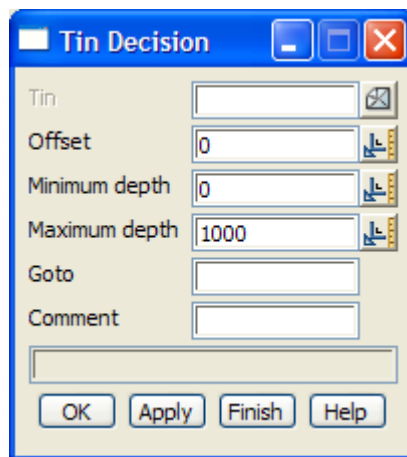

The format of the Tin Decision command in the panel is

Tin Decision *tin_name* Offset *value* Min *value* Max *value* Goto *label* // *comment*

The format of the command typed into the template file is

Tin_Decision *tin_name* *offset_value* *min_value* *max_value* *goto_label* // *comment*

The panel brought up when Tin decision is selected from the Create Rule menu is:

The fields and buttons used in this panel have the following functions.

Field Description	Type	Default	Pop-Up
Tin <i>the tin to calculate the depth to.</i>	input		available tins
Offset <i>the depth is calculate at an offset distance of offset from the end of the previous link.</i>	input	0	
Minimum depth <i>if the depth is between the minimum and maximum depth, then control is passed to the line with the</i>	input	0	

label given in the goto field, otherwise control passes onto the next line of the table.

Maximum depth input 1000

see previous field.

Goto input

label to go to if the depth is between the minimum and maximum depths.

Comment input

user comment - for information purposes only

OK/Apply button

OK stores the values in the fields and removes the panel.

Apply stores the values and leaves the panel on the screen.

Please continue to the next section "Batter Decision" .

Batter Decision

decision_batter_decision

Selecting Batter decision brings up the **Batter Decision** panel which is used to test whether a given link comes within

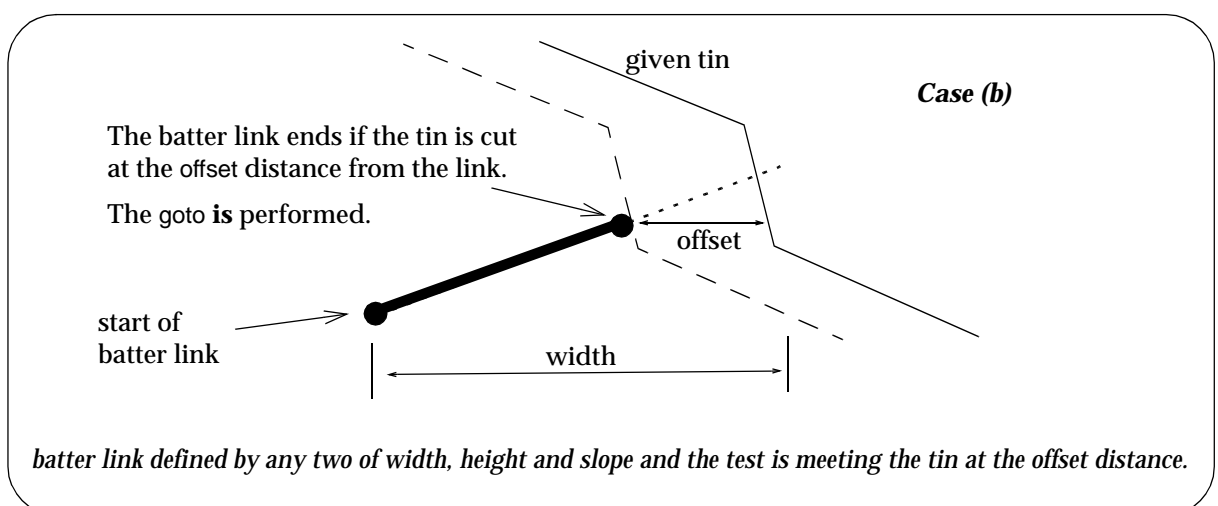

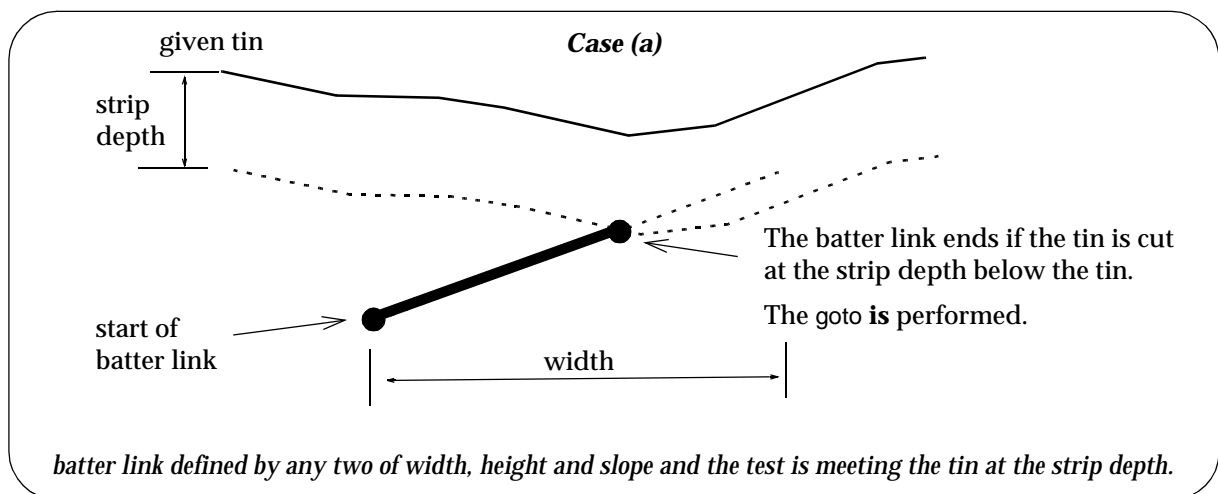

- (a) a strip depth of a tin
- (b) an offset distance from a tin.
- (c) a strip depth of a tin calculated at a given offset from the link.

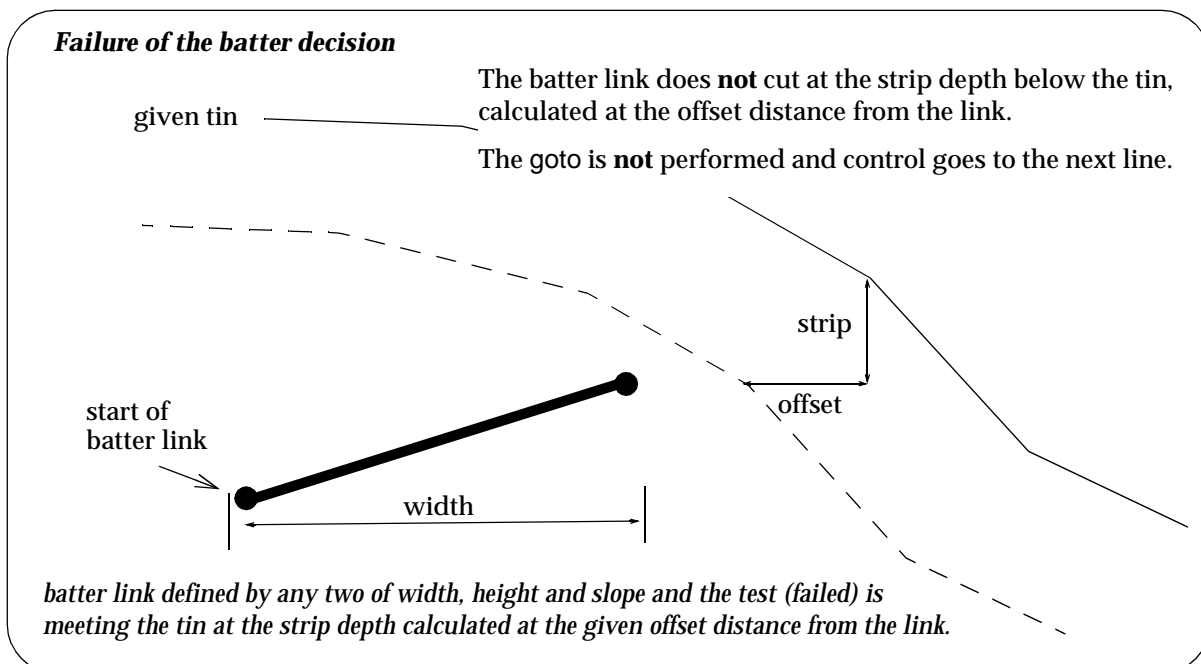

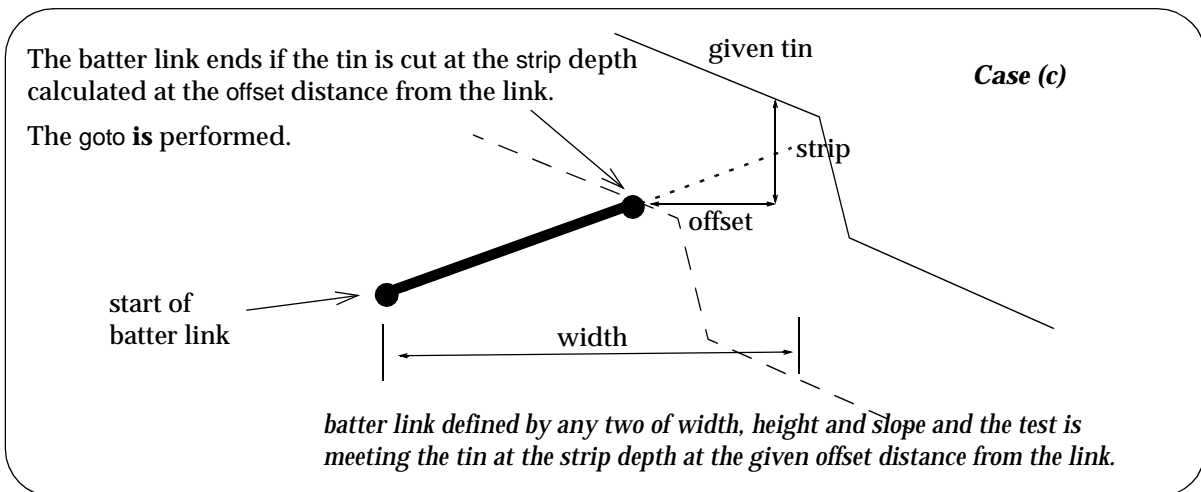

If the test is satisfied, then control is transferred via a goto, otherwise control continues onto the next line in the table.

The **test link** is defined by specifying values for two of the three fields width, height and slope.

Notes

1. no link is created, just the test is performed
2. cases (a) and (b) are just special cases of (c)
3. the batter decision is mainly used to test if a batter will stop without performing the batter.

The format of the Batter Decision command in the panel is

```
Batter Decision tin_name Strip value Offset value Width value Height value
Slope value Goto label // comment
```

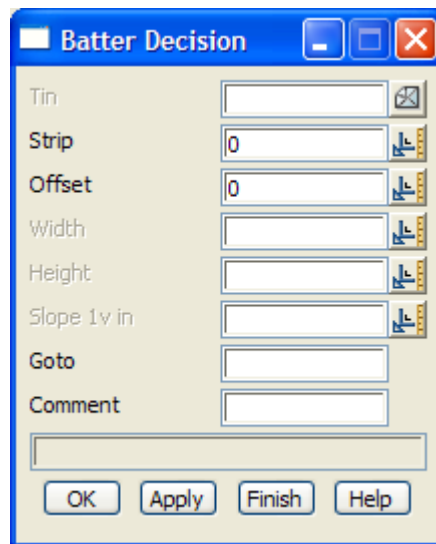

where only two of the three commands Width, Height and Slope are used.

The format of the command typed into the template file is

```
Batter_Decision tin_name strip_value offset_value width_value height_value slope_value
goto_label // comment
```

where one of *width_value*, *height_value* or *slope_value* is the key word *unknown*

The panel brought up when Batter decision is selected from the Create Rule menu is:

The fields and buttons used in this panel have the following functions.

Field Description	Type	Default	Pop-Up
Tin <i>tin to test the batter to.</i>	input		available tins
Strip <i>distance below the tin to stop at.</i>	input1	0	
Offset <i>offset distance from the link to check strip depth</i>	input1	0	
Width <i>the width for the link.</i>	input		
Height <i>the height for the link.</i>	input		
Slope 1v in <i>the slope, in 1v in, of the link. Positive is up and negative down.</i>	input		
Goto <i>label to goto if the test link comes within the strip depth of the tin at the given offset distance.</i>	input		
Comment <i>user comment - for information purposes only</i>	input		
OK/Apply	button		
<i>OK stores the values in the fields and removes the panel.</i>			
<i>Apply stores the values and leaves the panel on the screen.</i>			

Please continue to the next section "Batter" .

Batter

decision_batter

Selecting **Batter** brings up the **Batter** panel which is used to construct a link which stops if it comes within

- (a) a strip depth of a tin
- (b) an offset distance from a tin.
- (c) a strip depth of a tin calculated at a given offset from the link.

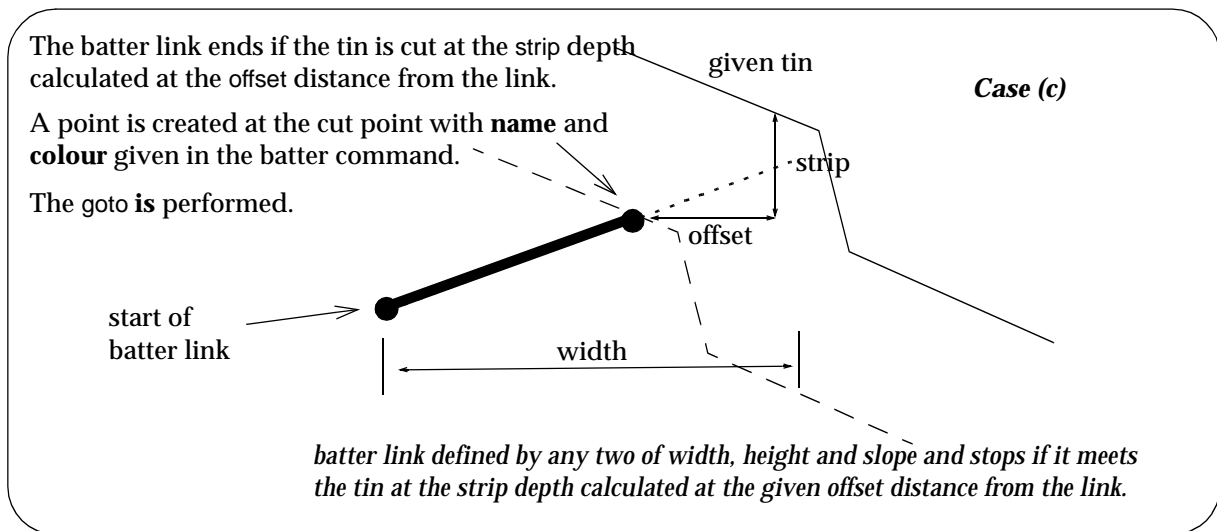

If the link does stop, control is transferred via a goto, otherwise control continues onto the next line in the table.

The batter link is defined by specifying values for two of the three fields width, height and slope.

Notes

1. cases (a) and (b) are just special cases of (c)
2. strip and offset can be used to stop the link to allow for a fixed structure (such as a drain) to be inserted so that it ends up on the tin.

The format of the Batter command in the panel is

```
Batter tin_name Strip value Width value Height value Slope value Name text
          Colour colour Goto label // comment
```

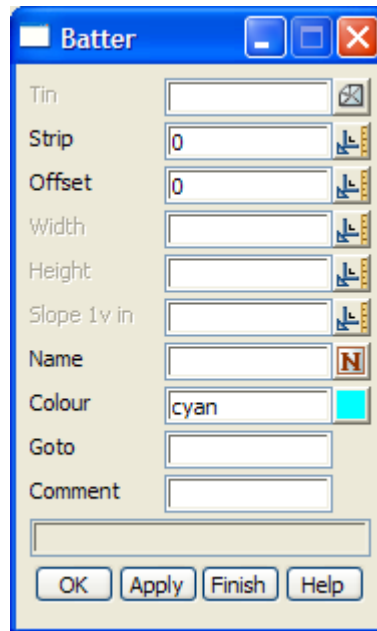

where only two of the three commands Width, Height and Slope are used.

The format of the command typed into the template file is

```
Batter tin_name strip_value width_value height_value slope_value
          name colour goto_label // comment
```

where one of *width_value*, *height_value* or *slope_value* is the key word *unknown*

The panel brought up when Batter is selected from the Create Rule menu is:

The fields and buttons used in this panel have the following functions.

Field Description	Type	Default	Pop-Up
Tin <i>tin to batter to.</i>	input		available tins
Strip <i>distance below the tin to stop at.</i>	input1	0	
Offset <i>offset distance from the link to check strip depth</i>	input1	0	
Width <i>the width for the link.</i>	input		
Height <i>the height for the link.</i>	input		
Slope 1v in <i>the slope, in 1v in, of the link. Positive is up and negative down.</i>	input		
Name <i>the name to be used for the created point and string.</i>	input		
Colour <i>the colour to be used for the created string</i>	input	cyan	available colours
Goto <i>label to goto if the batter link comes within the depth strip of the tin.</i>	input		
Comment <i>user comment - for information purposes only</i>	input		
OK/Apply	button		

OK stores the values in the fields and removes the panel.

Apply stores the values and leaves the panel on the screen.

Please continue to the next section “Label” .

Label

decision_label

Selecting Label brings up the **Label** panel which is used to define a label for the line for which control can be passed to via a goto.

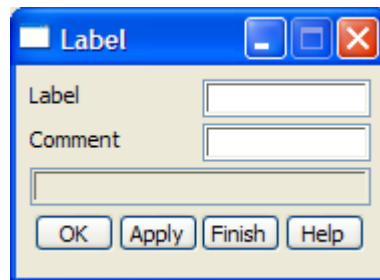

The format of the Label command in the panel is

```
Label label_name // comment
```

The format of the command typed into the template file is

```
Label label_name // comment
```

The panel brought up when Label is selected from the Create Rule menu is:

The fields and buttons used in this panel have the following functions.

Field Description	Type	Default	Pop-Up
Label <i>name of the label for the line in the table.</i>	input		
Comment <i>user comment - for information purposes only</i>	input		
OK/Apply <i>OK stores the values in the fields and removes the panel. Apply stores the values and leaves the panel on the screen.</i>	button		

Please continue to the next section "Goto".

Goto

decision_goto

Selecting Goto brings up the **Goto** panel which is used to transfer control to the line with the label given in the goto field of the panel.

The format of the Goto command in the panel is

```
Goto label_name // comment
```

The format of the command typed into the template file is

```
Goto label_name // comment
```

The panel brought up when Goto is selected from the Create Rule menu is:

The fields and buttons used in this panel have the following functions.

Field Description	Type	Default	Pop-Up
-------------------	------	---------	--------

Goto	input		
<i>name of the label to transfer control to.</i>			

Comment	input		
<i>user comment - for information purposes only</i>			

OK/Apply	button		
<i>OK stores the values in the fields and removes the panel.</i>			
<i>Apply stores the values and leaves the panel on the screen.</i>			

Please continue to the next section “Undo” .

Undo

decision_undo

Selecting **undo** brings up the **Undo Decision** panel which is used to delete a given number of points (and hence links) from the template being constructed.

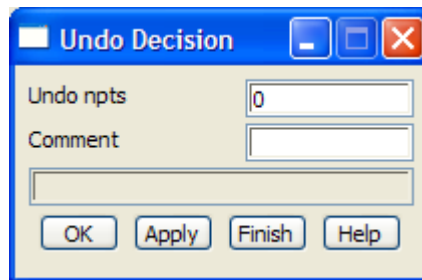

The format of the Label command in the panel is

Undo *number_of_points* // *comment*

The format of the command typed into the template file is

Undo *number_of_links* // *comment*

The panel brought up when **Undo** is selected from the Create Rule menu is:

The fields and buttons used in this panel have the following functions.

Field Description	Type	Default	Pop-Up
Undo npts <i>number of points to delete from the template.</i>	input	0	
Comment <i>user comment - for information purposes only</i>	input		
OK/Apply <i>OK stores the values in the fields and removes the panel.</i> <i>Apply stores the values and leaves the panel on the screen.</i>	button		

Please continue to the next section “Comment” .

Comment

decision_comment

Selecting **Comment** brings up the **Comment** panel and inserts an comment into the line of the table. Comments are ignored by the decisions calculations.

The panel brought up when **Comment** is selected from the Create Rule menu is:

The fields and buttons used in this panel have the following functions.

Field Description	Type	Default	Pop-Up
Comment <i>user comment - for information purposes only</i>	input		
OK/Apply OK stores the values in the fields and removes the panel. Apply stores the values and leaves the panel on the screen.	button		

Please continue to the next section “End” .

End

decision_end

Selecting **End** brings up the **End** panel and inserts an end command into the line of the table. When control reaches an **end** command, the decisions calculations are terminated.

The format of the End command in the panel is

End // comment

The format of the command typed into the template file is

End // comment

The panel brought up when **End** is selected from the Create Rule menu is:

The fields and buttons used in this panel have the following functions.

Field Description	Type	Default	Pop-Up
Comment <i>user comment - for information purposes only</i>	input		
OK/Apply OK stores the values in the fields and removes the panel. Apply stores the values and leaves the panel on the screen.	button		

Please continue to the next section “Decisions Examples” .

Decisions Examples

One Tin Example

```

//From: 12D Solutions
//Date: 11/07/97
//
//Basic Decisional Template for cut in 9m depth, 5m depth, and less
//Note the Tin Used is "SURVEY"
//
//
template "std" {

Placing Elements for Super Alignments

Placing a super alignment, like the alignment strings, consists of:

- (a) defining the horizontal geometry
- (b) defining the vertical geometry

Unlike the alignment which uses IP methods only, the super alignment allows the user to partially define elements making up the super alignment. The position and types of elements, and the condition that each element is tangential to the adjacent elements, may allow *12d Model* to calculate for all the unknowns in the element definitions to be solved and the super alignment be fully defined.

Horizontal elements consist of lines, arcs and transition spirals.

Normally these elements can be combined in the super alignment and defined so that adjacent elements are tangential to each other.

When placing horizontal elements, *12d Model* often only requires **some** of the information defining the element and the configuration of the elements and enforcing tangentiality of adjacent elements, allows *12d Model* to calculate the rest of the information.

Vertical elements consist of lines, parabolas and arcs.

These elements can be combined in the super alignment and defined so that adjacent elements are tangential to each other.

When placing vertical elements, *12d Model* often only requires **some** of the information defining the element and the configuration of the elements and enforcing tangentiality of adjacent elements, allows *12d Model* to calculate the rest of the information.

Horizontal IP's

No curve, go to No curve - known horizontal intersection point with no arc on it

Alignment speed, go to Alignment speed - known horizontal intersection point with arcs and spirals defined by the design parameters and default speed for the super alignment

Curve speed, go to Curve speed - known horizontal intersection point with known speed with the arcs and spirals are defined by design parameters for that speed

Curve length, go to Curve length - known horizontal intersection point with an arc of a known length

Curve radius, go to Curve radius - known horizontal intersection point with an arc of a known radius

Curve spiral, go to Curve spiral - known horizontal intersection point with an arc of a known radius and leading and trailing spirals of known lengths.

Horizontal Lines

Fixed, go to Fixed - line passes through two known points

Fixed direction, go to Fixed direction - the line passes through a known point with a known bearing. An offset is allowed.

Floating point, go to Floating point - the line passes through a known point but the bearing is unknown bearing

Floating direction, go to Floating direction - the line has a known bearing but nothing else is known

Floating end, go to Floating end - the line has a known length and goes from the end of a previous element

Free, go to Free - the line is not constrained in any way

Horizontal Arcs

Fixed, go to Fixed - the arc centre is known as well as the radius and start and end points. An offset is allowed.

Fixed 3 points, go to Fixed 3 points- the arc passes through three known points

Fixed direction, go to Fixed direction- known point, known radius and known bearing at the known point

Floating radius, go to Floating radius - the radius of the arc is known and the arc passes through a known point

Floating direction, go to Floating direction - the arc passes through a known point with a known bearing at the point

Floating 2 pts, go to Floating 2 points- the arc passes through two known points

Floating end and point, go to Floating end and point- the arc passes through one known point and is attached to either previous or next element

Floating end, radius and length, go to Floating end, radius and length- the arc has a known radius and a known length

Free radius, go to Free radius - the arc has a known radius

Free point, go to Free point - the arc passes through a known point

Free length, go to Free length - the arc has a known length

Horizontal Transitions

Free spiral, go to Free spiral - the transition spiral is unconstrained

Spiral, go to Spiral - the spiral has a known length

Back to back, go to Back to back- back to back spirals of known lengths between two fixed lines

Arc to arc, go to Arc to arc- back to back spirals between known arcs. One spiral length is needed.

Taper, go to Taper - known length and known ratio

None, go to None - no transition

3 centred, go to 3 centred - three centred curve - three arcs with given radii and offsets

2 centred, go to 2 centred - two centred curve- two arcs with given radii

Compound spiral, go to Compound spiral - compound spirals of known lengths

Compound line, go to Compound line - compound spirals with one known length with a line of known length

Compound arc, go to Compound arc - compound arcs of known radii

Vertical IP's

No VC, go to No VC - known vertical intersection point with no parabola or arc on it

Alignment speed, go to Alignment speed - known vertical intersection point with parabola defined by the design parameters and default speed for the super alignment

Speed, go to Speed - known vertical intersection point with a known speed and the parabolic curve defined by the design parameters

Length, go to Length - known vertical intersection point with a parabola of a known length

Radius, go to Radius - known vertical intersection point with a parabola of a known effective radius

K value, go to K-value - known vertical intersection point with a parabola of a known k-value

Max length, go to Max length - known vertical intersection point with a parabola of maximum length

Asymmetric, go to Asymmetric - known vertical intersection point with asymmetric parabolas of known lengths

Circular arc, go to Circular arc - known vertical intersection point with an arc of a known radius

Vertical Lines

Fixed, go to Fixed - two known points

Fixed grade, go to Fixed grade - known point and know grade

Floating point, go to Floating point - known point (unknown grade)

Floating grade, go to Floating grade - known grade (unknown point)

Free, go to Free - not constrained at all

Vertical Arcs

Fixed, go to Fixed - known centre, known radius and known start and end points of the arc

Fixed 3 points, go to Fixed 3 points- three known points on the arc

Fixed direction, go to Fixed direction- known point, known radius and known bearing at the known point

Floating radius, go to Floating radius - known point and known radius of the arc

Floating grade, go to Floating grade - known point and known tangential grade of the arc at the known point

Floating 2 points, go to Floating 2 points- two known points on the arc

Free radius, go to Free radius - known radius of the arc

Free point, go to Free point - known point on the arc

Free length, go to Free length - known length of the arc

Vertical Parabolas

Fixed 3 points, go to Fixed 3 points- three known points on the parabola

Fixed apex radius, go to Fixed apex radius- known apex point and known effective radius of the parabola

Floating 2 points, go to Floating 2 points- two known points on the parabola

Floating apex, go to Floating apex- known apex point of the parabola

Floating radius, go to Floating radius - known point and known effective radius of the parabola

Floating grade, go to Floating grade - known point and known grade at the known point

Floating k value, go to Floating k value - known point and known k value of the parabola

Free point, go to Free point - known point on the parabola

Free length, go to Free length - known length of the parabola

Free radius, go to Free radius - known effective radius of the parabola

Free rl, go to Free rl - known height of the parabola

Free k value, go to Free k value- known k value of the parabola

Free max length, go to Free max length- fit a parabola of maximum length

Free asymmetric, go to Free asymmetric- asymmetric parabolas of known lengths

Free compound, go to Free compound- compound parabolas with a percentage length of the first parabola and an optional total length

Super Alignment Horizontal Elements

Horizontal IP's

No curve - known horizontal intersection point with no arc on it

Horizontal IP's

Alignment speed - known horizontal intersection point with arcs and spirals defined by the design parameters and default speed for the super alignment

Horizontal IP's

Curve speed - known horizontal intersection point with known speed with the arcs and spirals are defined by design parameters for that speed

Horizontal IP's

Curve length - known horizontal intersection point with an arc of a known length

Horizontal IP's

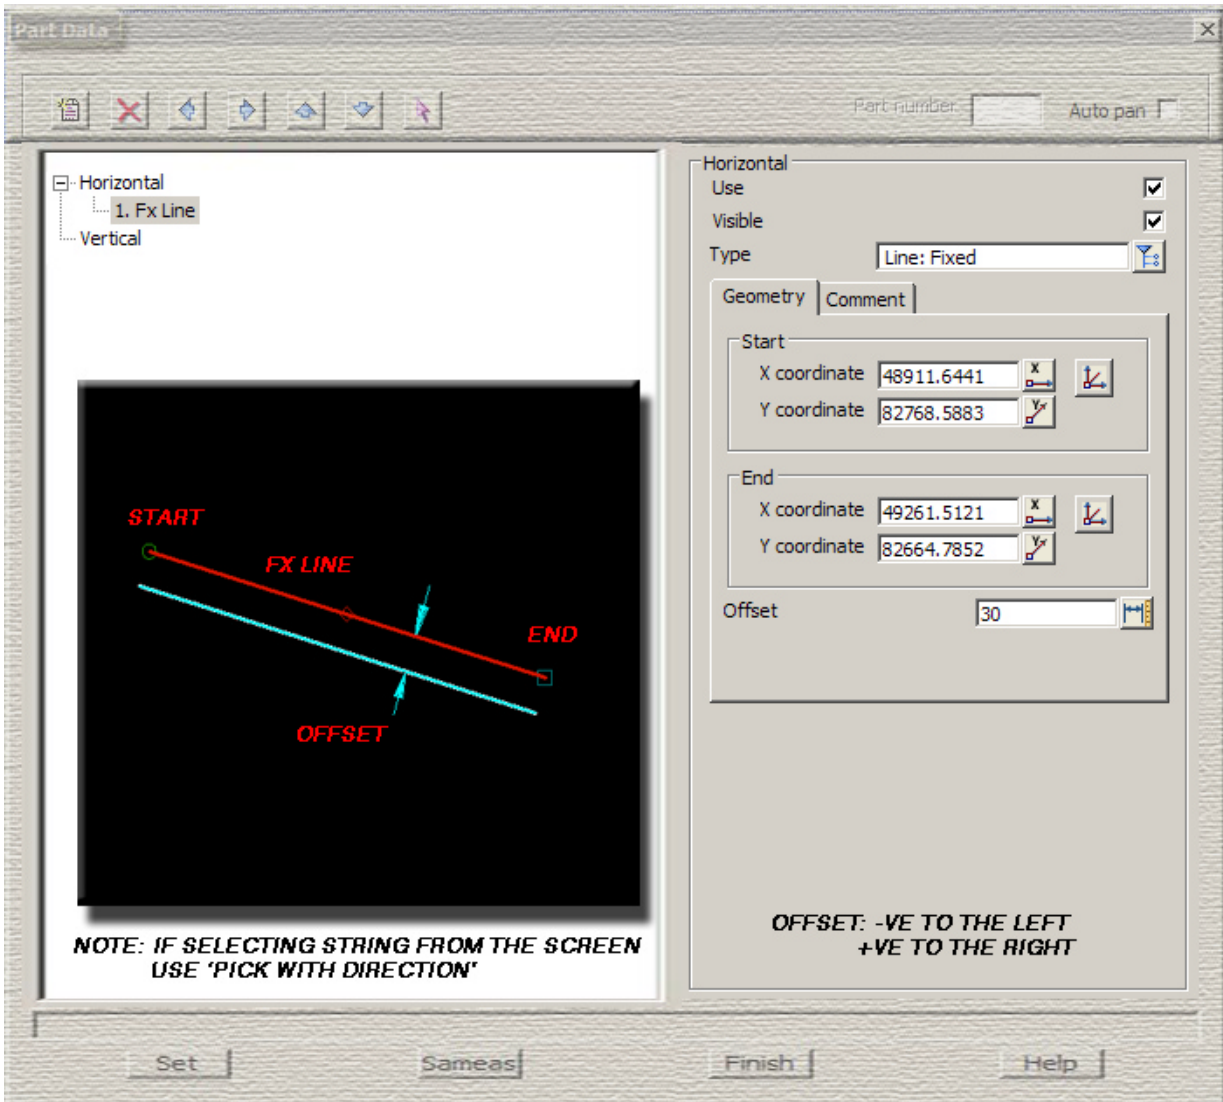

Curve radius - known horizontal intersection point with an arc of a known radius

Horizontal IP's

Curve spiral - known horizontal intersection point with an arc of a known radius and leading and trailing spirals of known lengths.

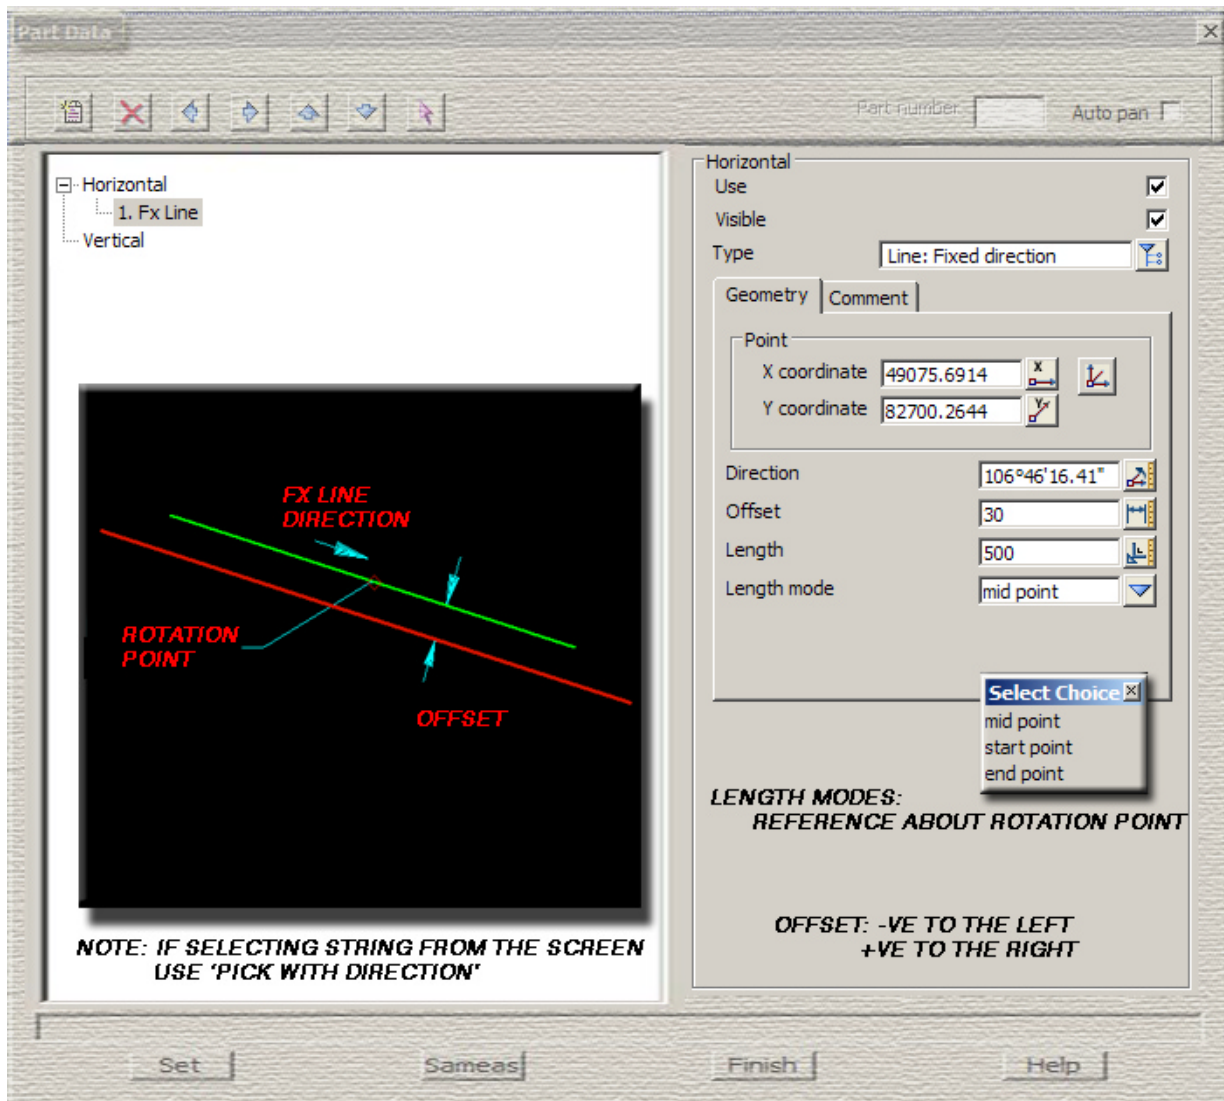

Horizontal Lines

Fixed - line passes through two known points

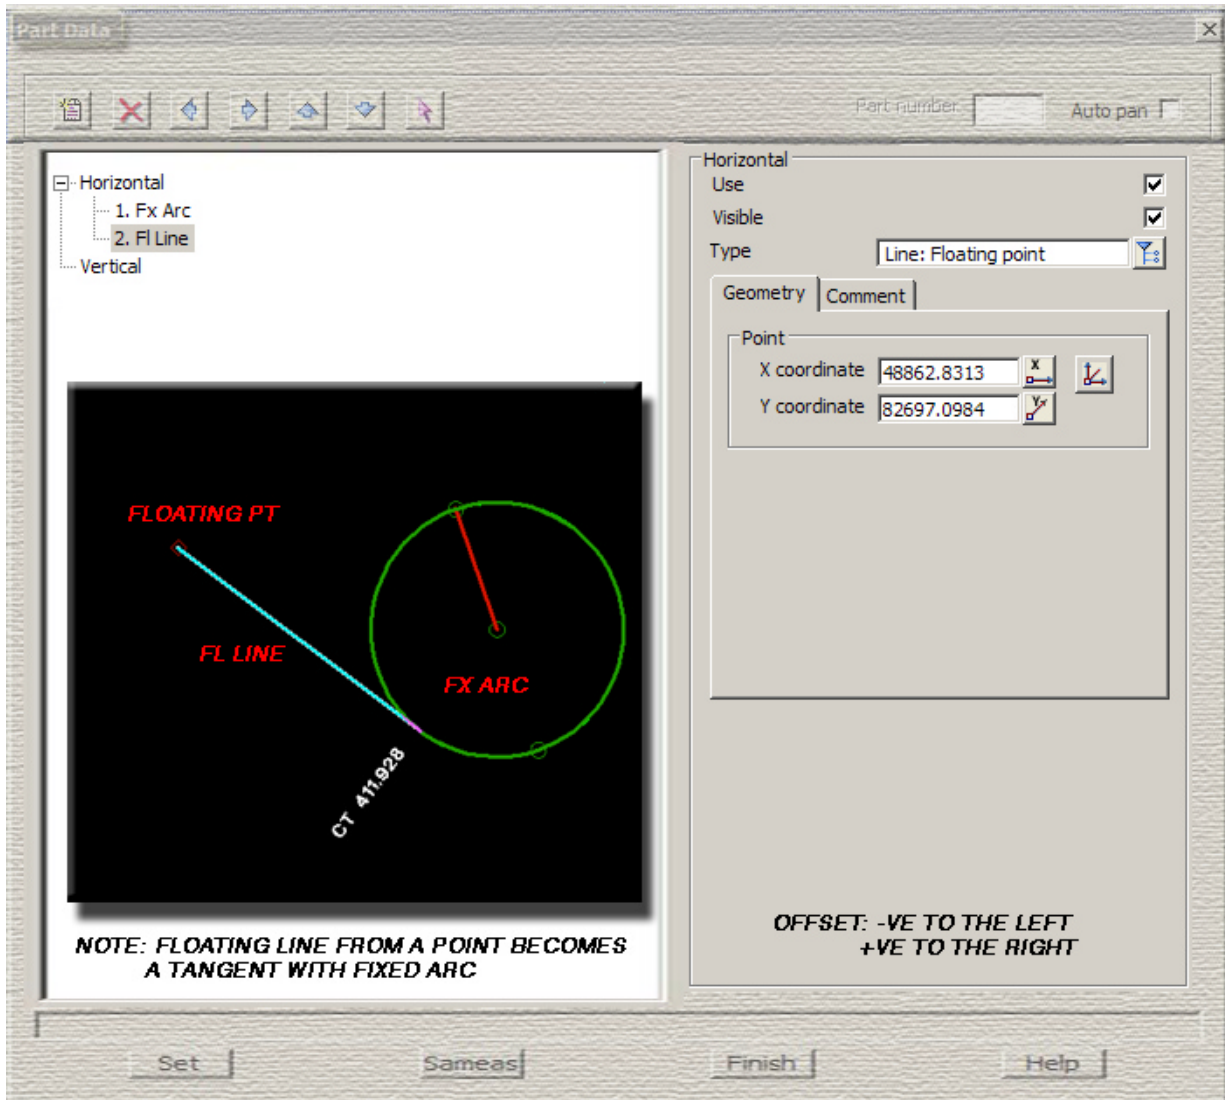

Horizontal Lines

Fixed direction - the line passes through a known point with a known bearing. An offset is allowed.

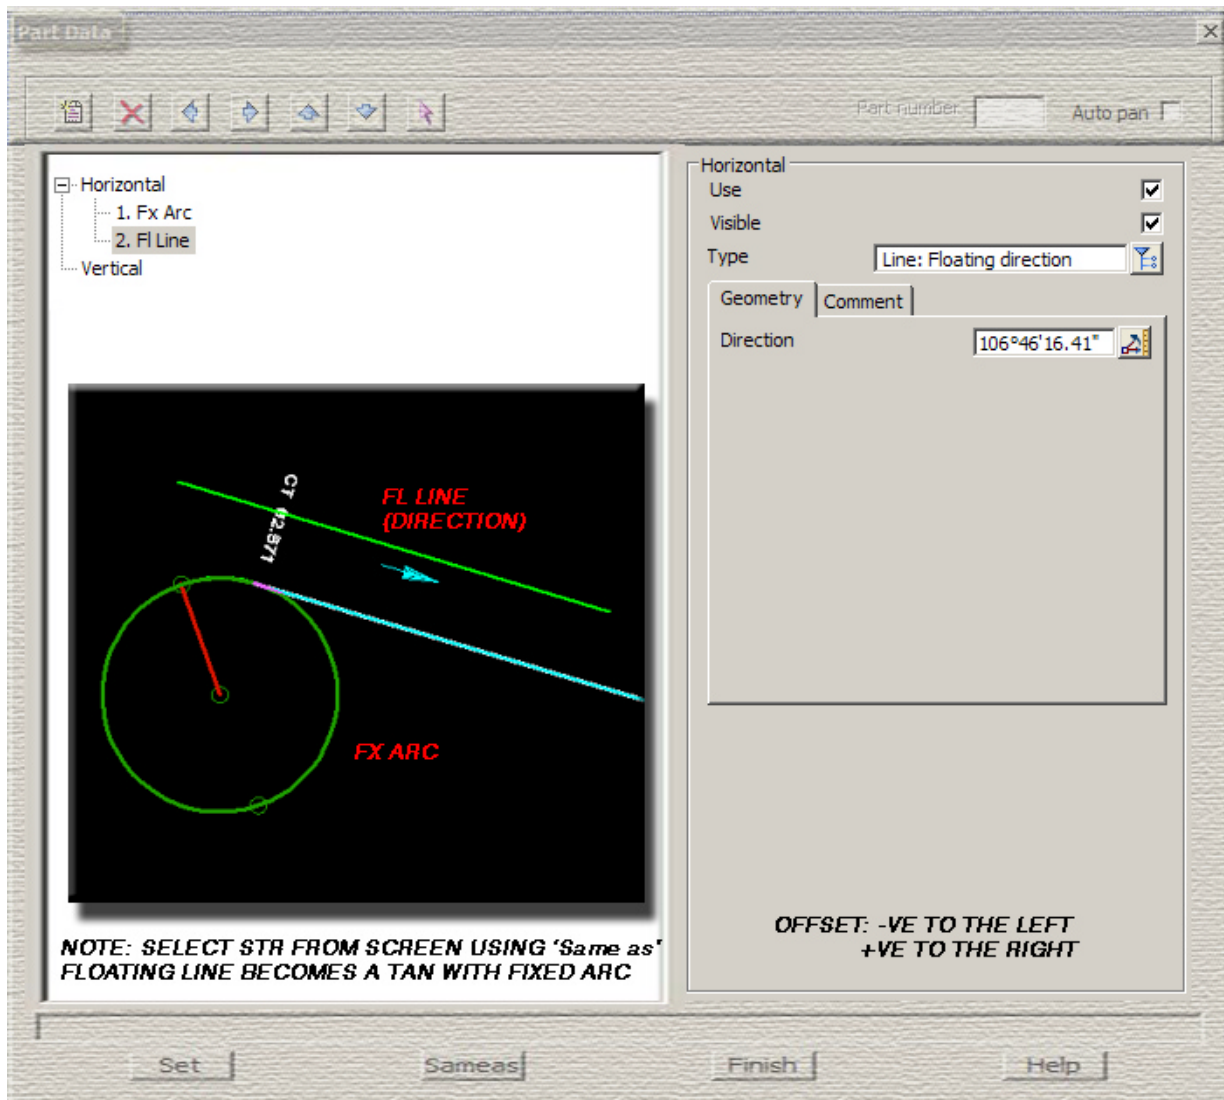

Horizontal Lines

Floating point - the line passes through a known point but the bearing is unknown bearing

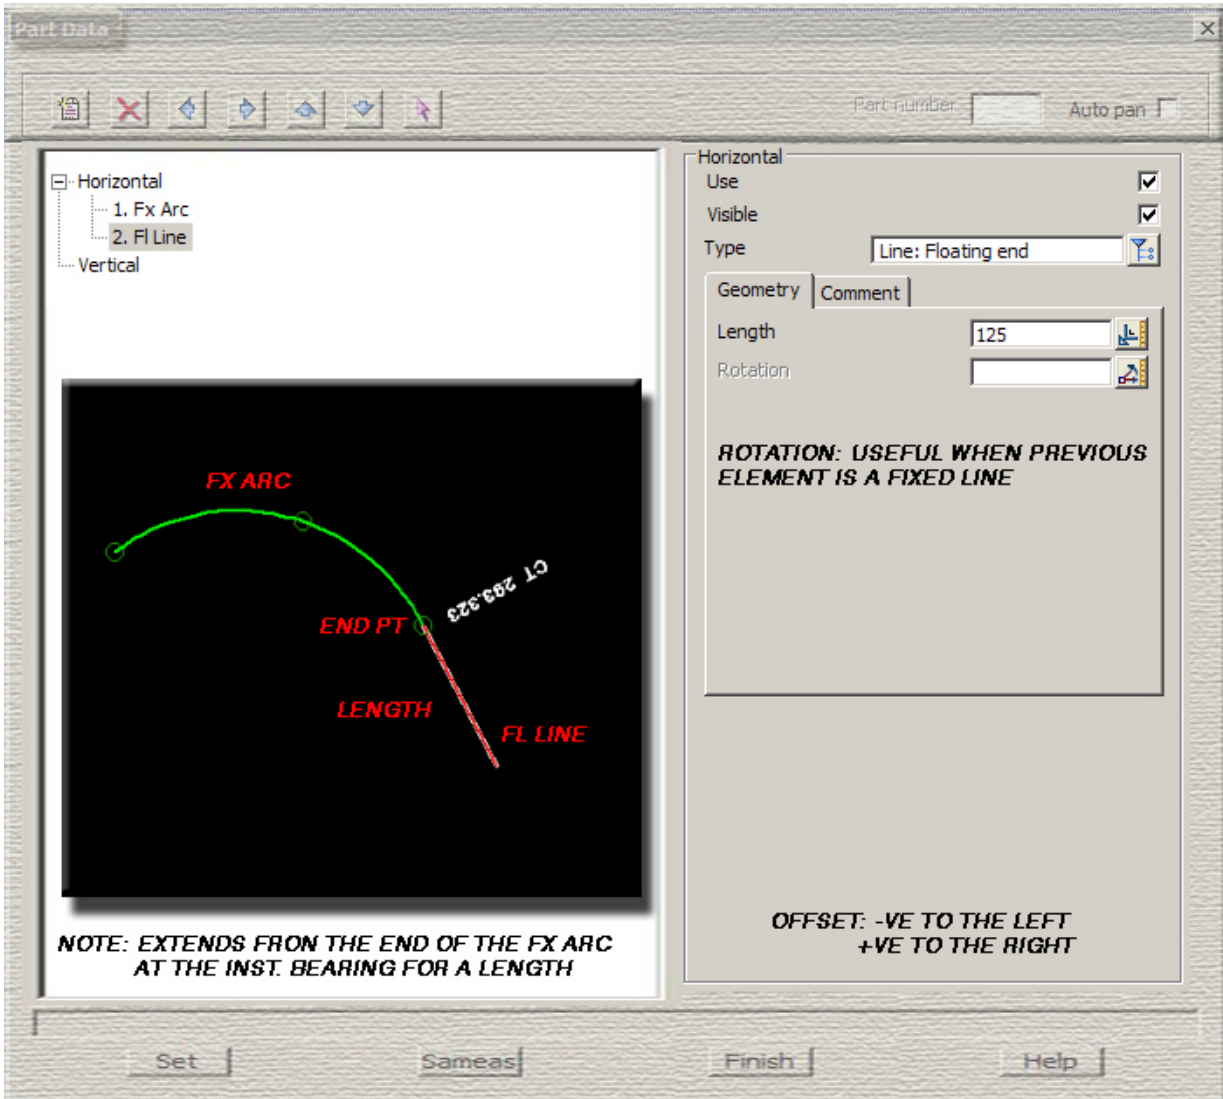

Horizontal Lines

Floating direction - the line has a known bearing but nothing else is known

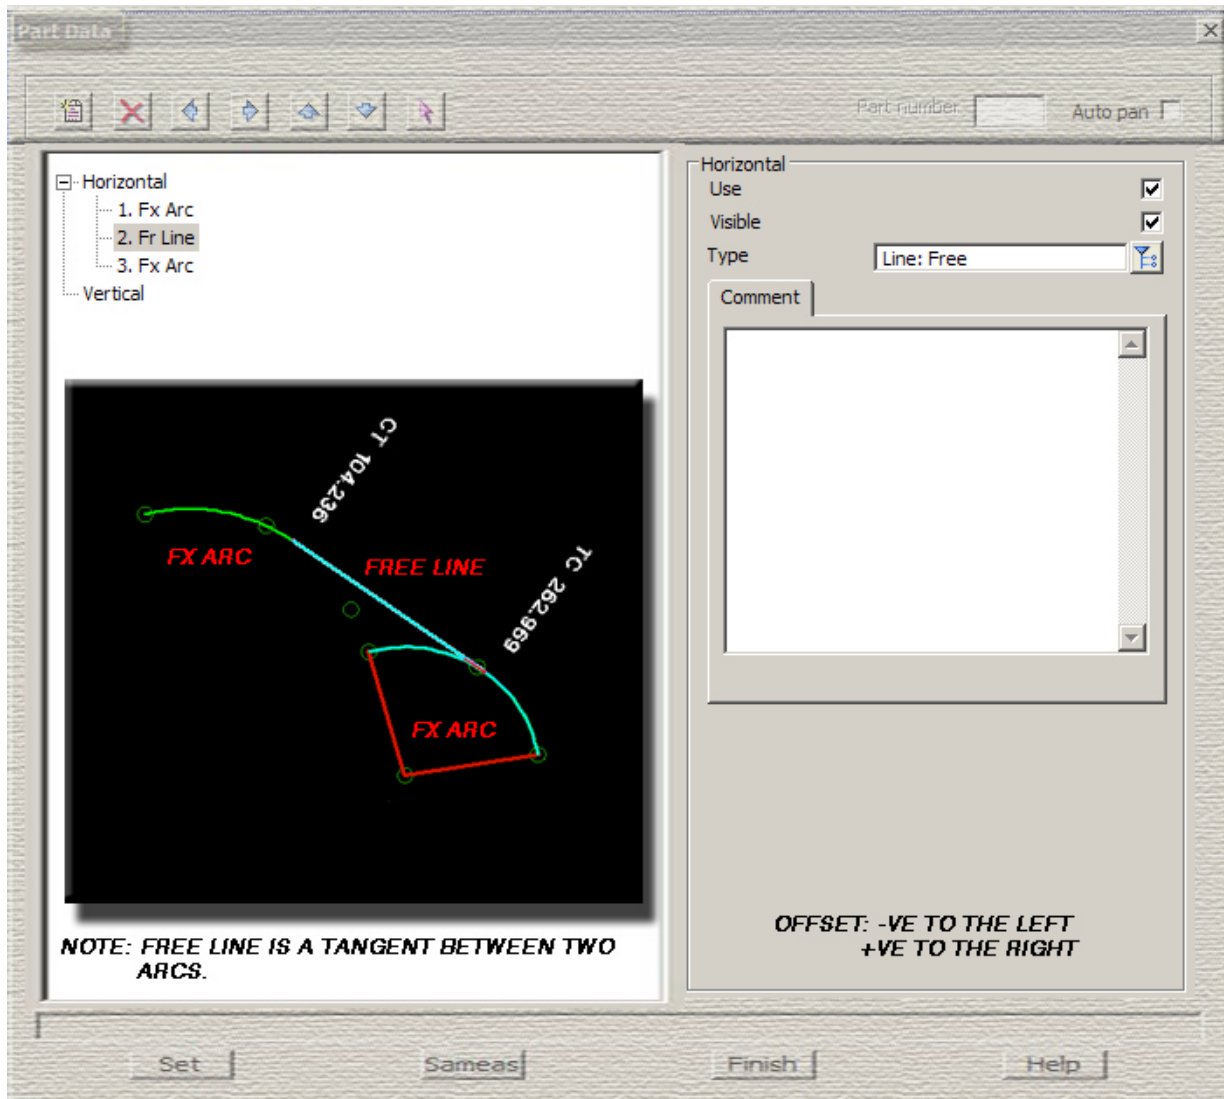

Horizontal Lines

Floating end - the line has a known length and goes from the end of a previous element

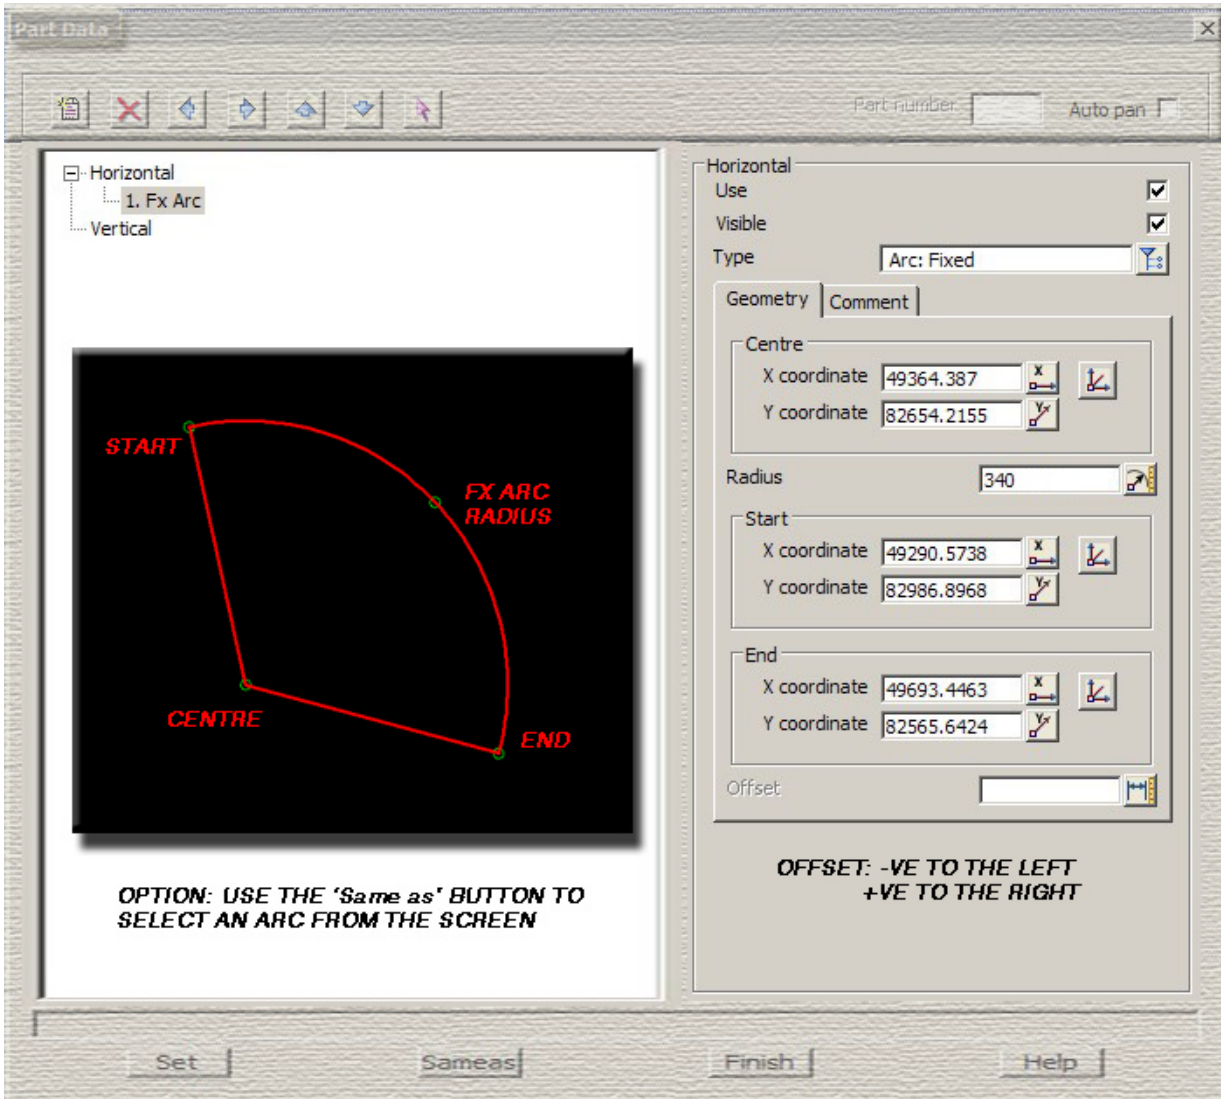

Horizontal Lines

Free - the line is not constrained in any way

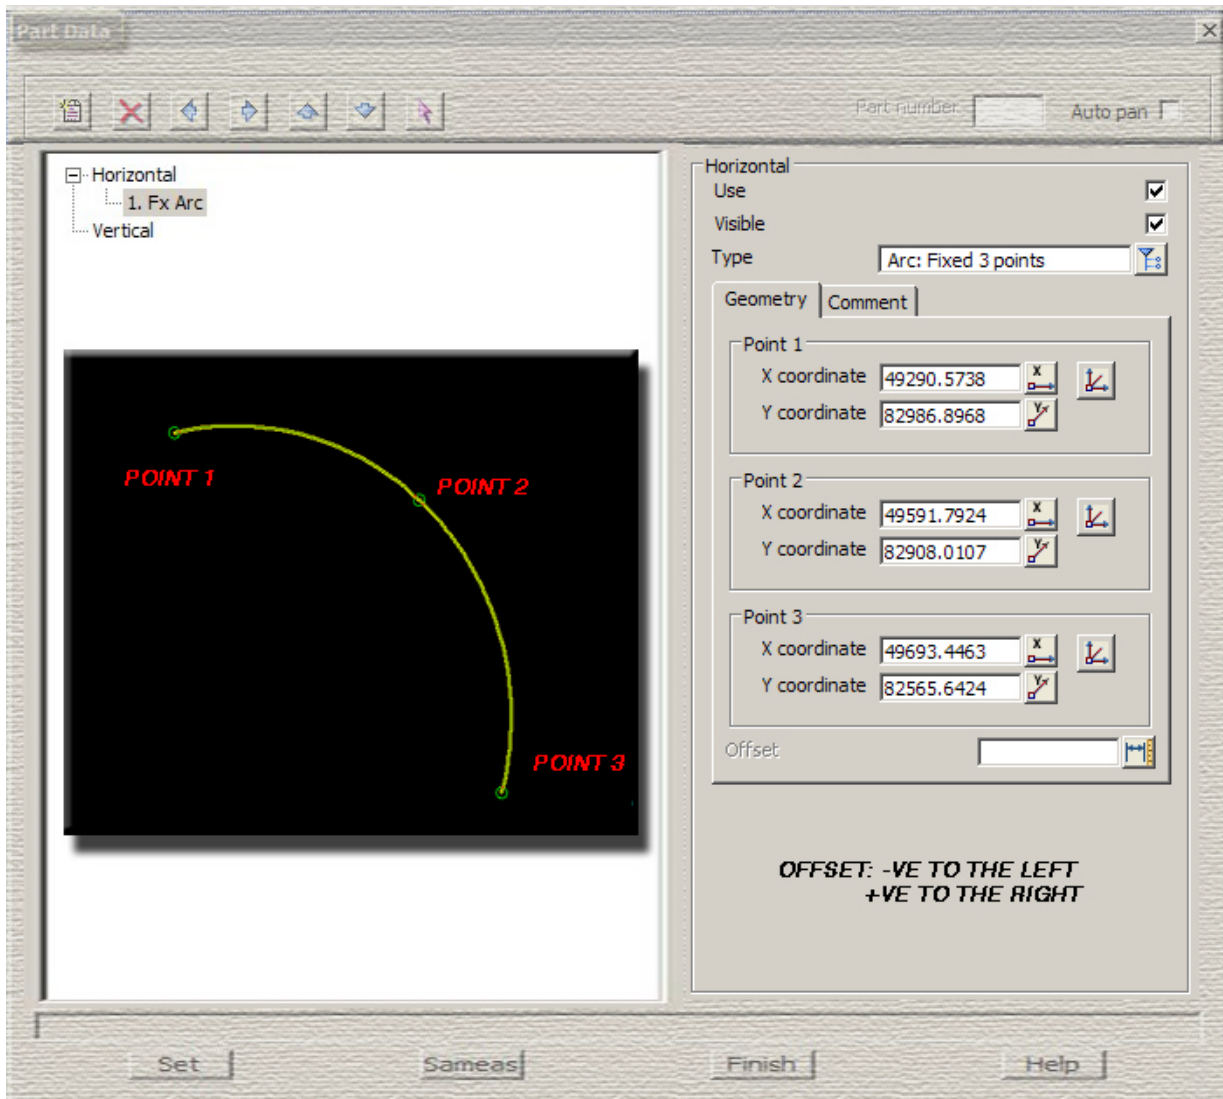

Horizontal Arcs

Fixed - the arc centre is known as well as the radius and start and end points. An offset is allowed.

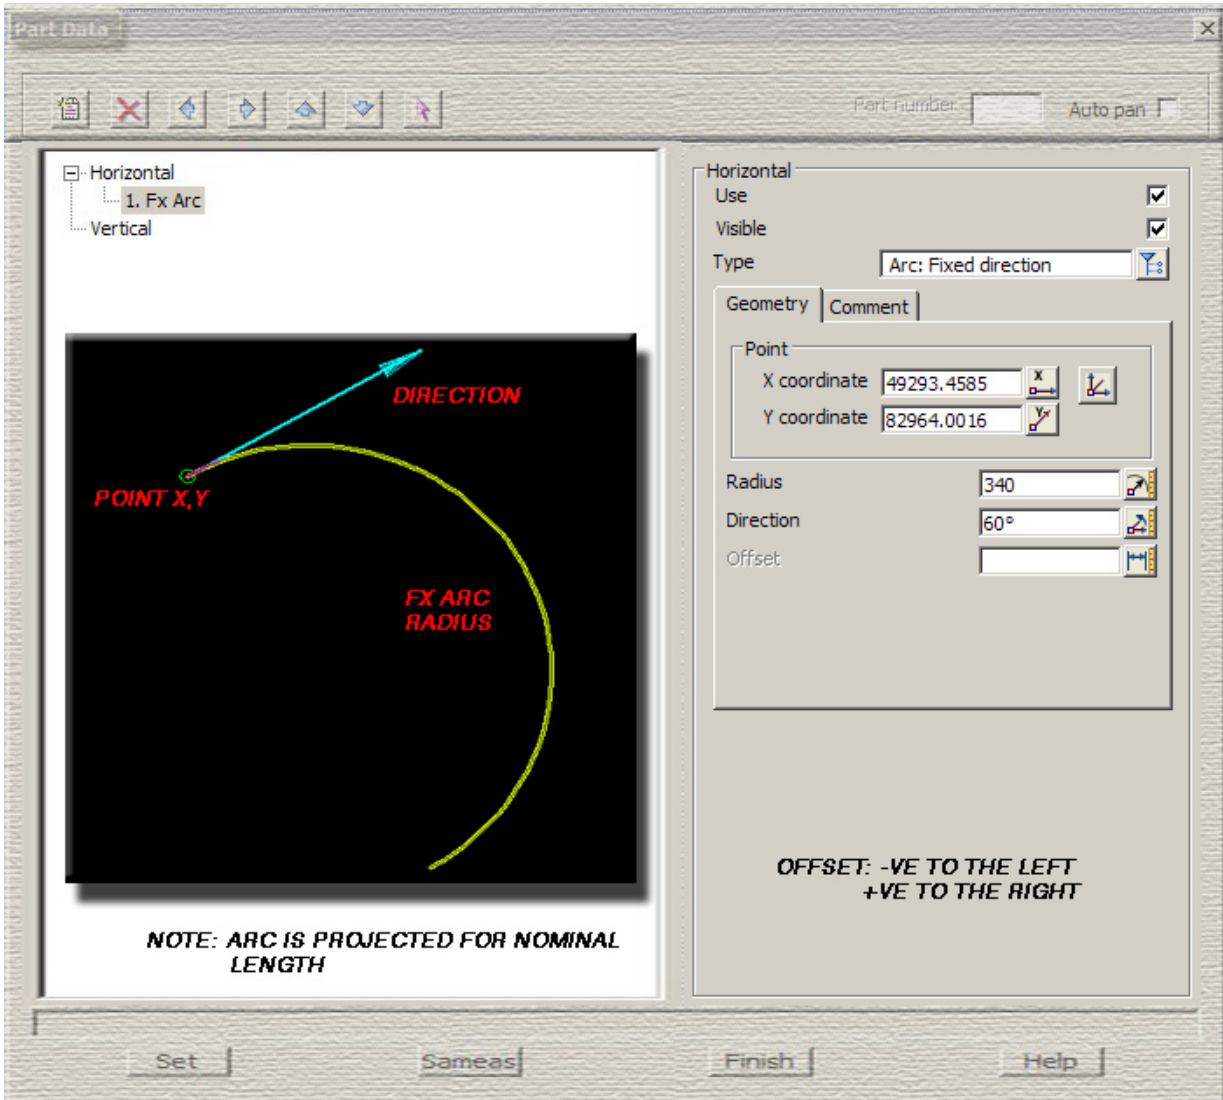

Horizontal Arcs

Fixed 3 points- the arc passes through three known points

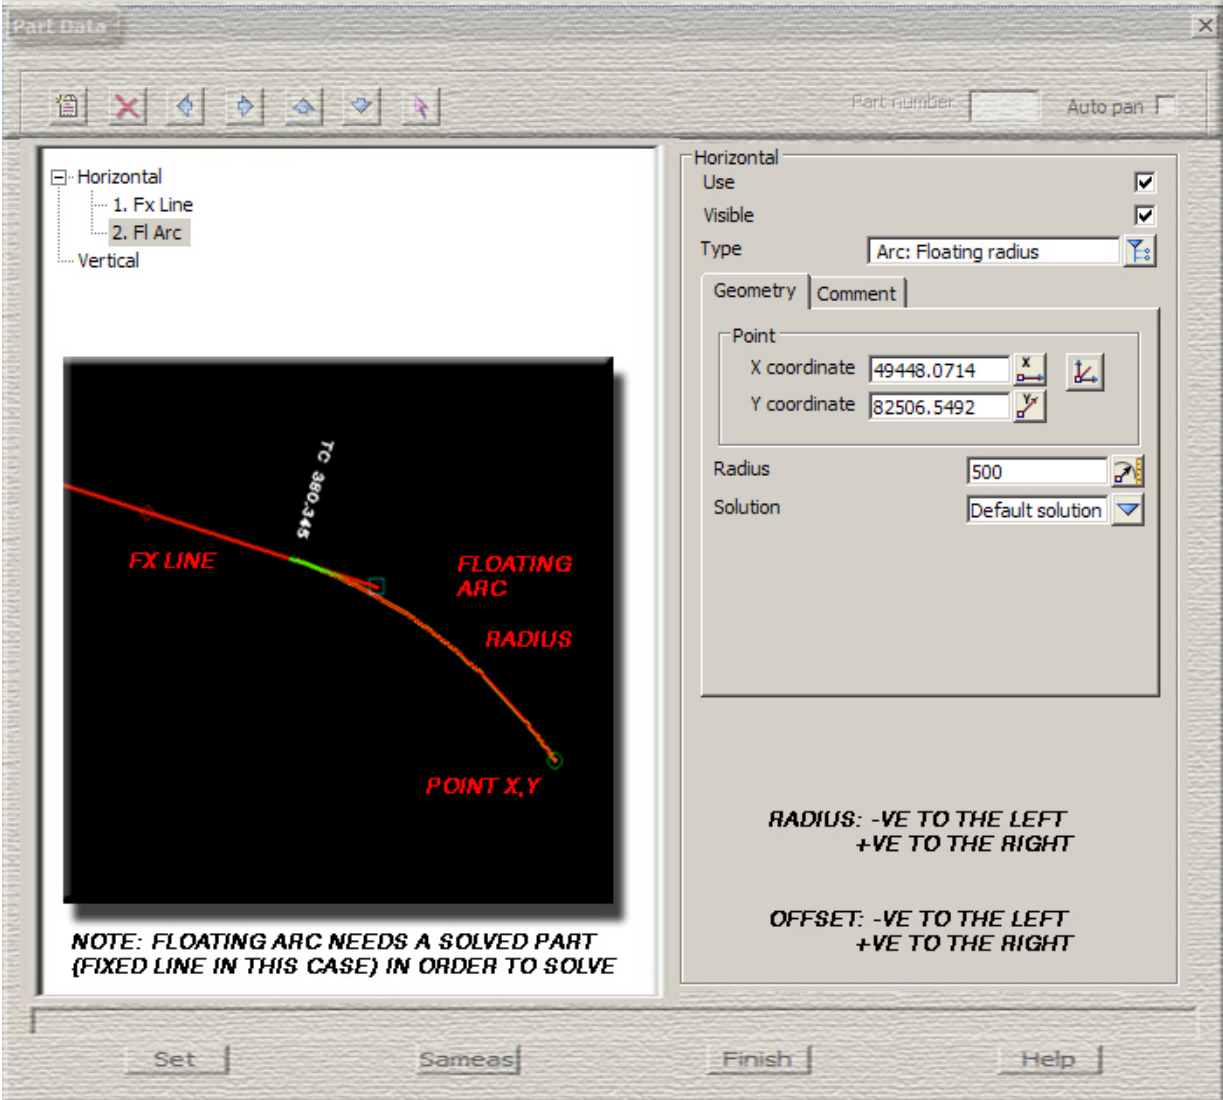

Horizontal Arcs

Fixed direction- known point, known radius and known bearing at the known point

Horizontal Arcs

Floating radius - the radius of the arc is known and the arc passes through a known point

Horizontal Arcs

Floating direction - the arc passes through a known point with a known bearing at the point

The screenshot displays a software window titled "Part Data" with a toolbar at the top. The main area is divided into a graph and a control panel.

Graph: A graph showing a vertical alignment design. The horizontal axis represents chainage, with a central point at 68.537L. The vertical axis represents elevation. A red line represents the "FL LINE" (Floating Line), which is a straight line segment. A blue curve represents the "FL PARABOLA" (Floating Parabola). The graph is divided into three sections: "FX LINE" (left), "FL PARABOLA" (middle), and "PT" (right). The grades are indicated as -3% on the left and 6.138% on the right. A note at the bottom of the graph reads: "NOTE: TYPICAL APPLICATION FLOATING LINE ATTACHED TO SOLVED PARABOLA".

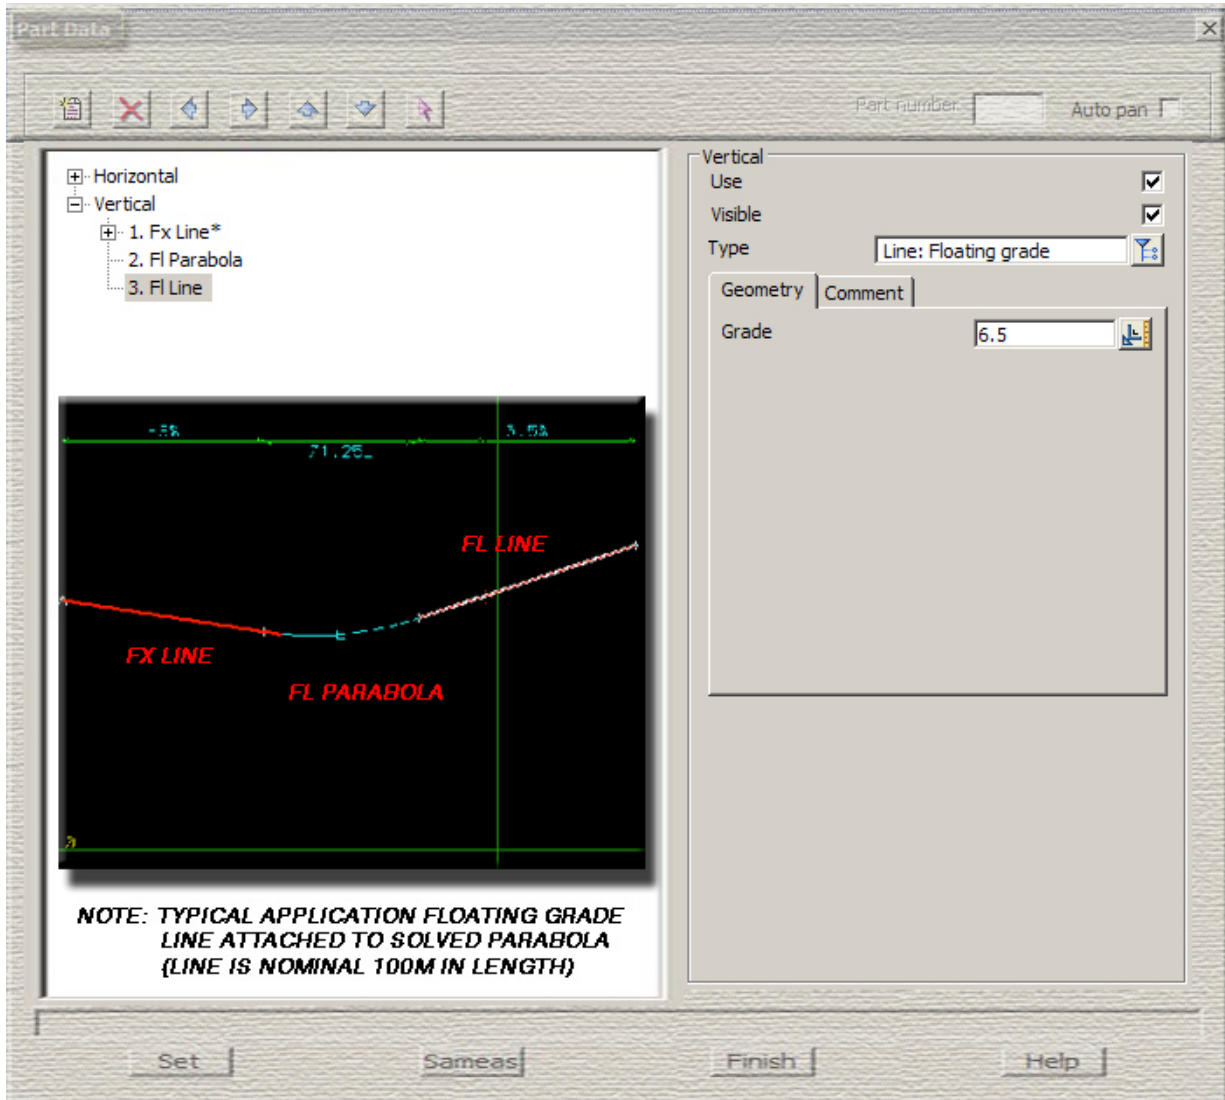

Control Panel: The right side of the window contains a control panel for the "Line: Floating point". It includes the following fields and controls:

- Vertical Use:**
- Visible:**
- Type:** Line: Floating point
- Geometry / Comment:** A tabbed interface with "Geometry" selected.
- Point:** A section with two input fields:
 - Chainage:** 194.6317
 - Height:** 22.4177

At the bottom of the window, there are four buttons: "Set", "Sameas", "Finish", and "Help".

Floating radius - known point and known effective radius of the parabola

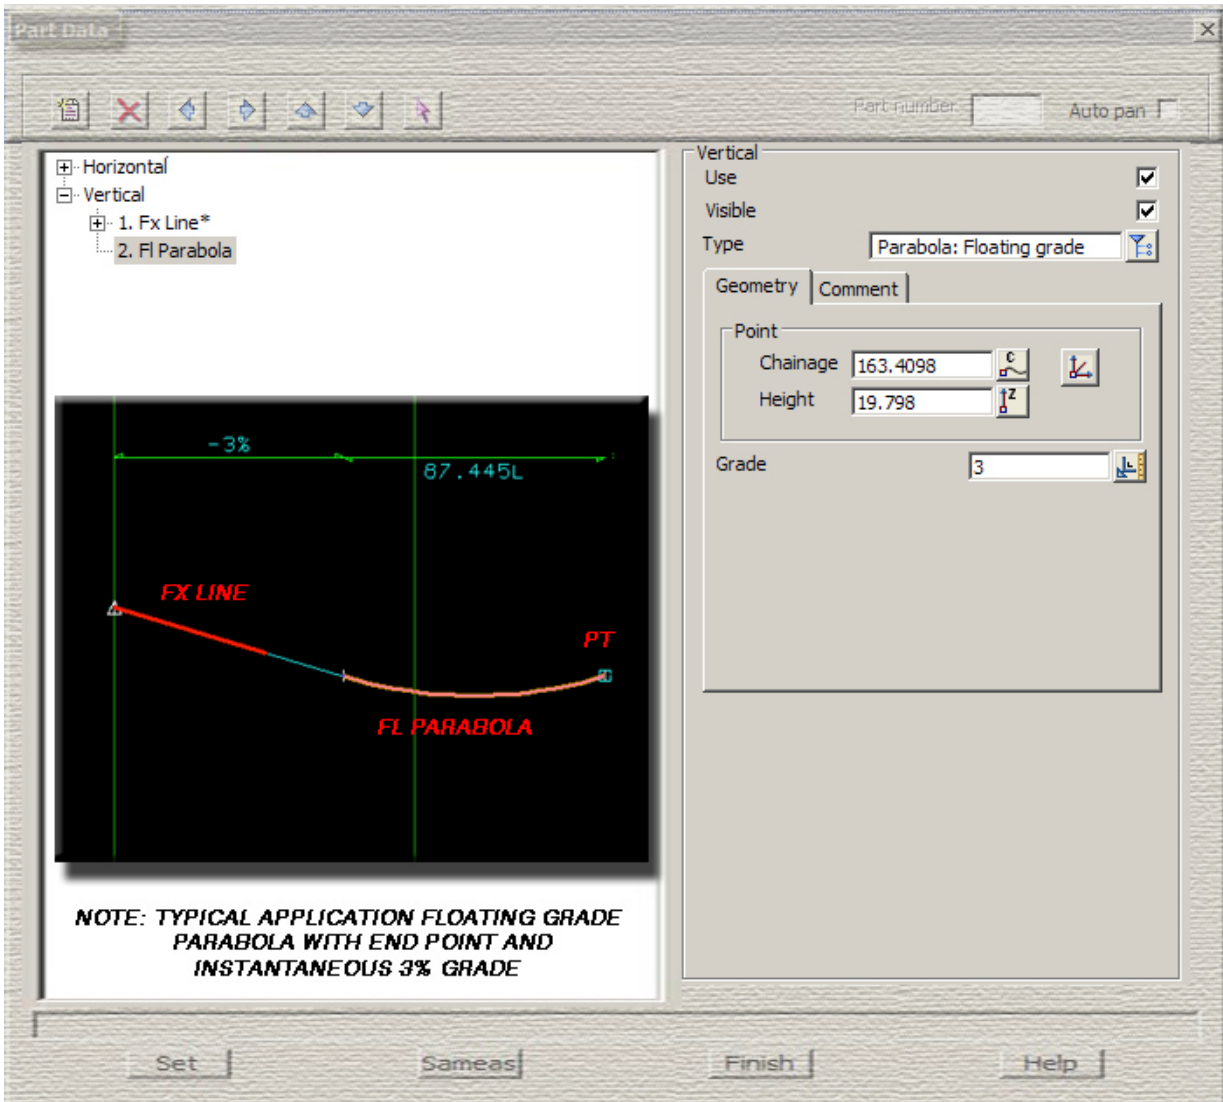

The screenshot shows the 'Part Data' dialog box for a vertical parabola. The left pane shows a tree view with 'Vertical' expanded to show '1. Fx Line*', '2. Fl Parabola', and '3. Fl Line'. The main window displays a graph with a black background. A red line labeled 'FX LINE' slopes downward from left to right. A blue line labeled 'FL LINE' slopes upward from left to right. A red parabolic curve labeled 'FL PARABOLA' is positioned between the two lines, passing through a point labeled 'PT'. The graph shows a horizontal distance of '120L' between the two lines, with a slope of '-3%' on the left and '3%' on the right. The right pane contains the following settings:

- Vertical Use:
- Visible:
- Type: Parabola: Floating radius
- Geometry tab selected
- Point:
 - Chainage: 143.3289
 - Height: 19.4727
- Radius: 2000

At the bottom of the dialog, there are buttons for 'Set', 'Sameas', 'Finish', and 'Help'. A note at the bottom of the main window reads: 'NOTE: TYPICAL APPLICATION FLOATING RADIUS PARABOLA THROUGH A POINT BETWEEN FIXED & FLOATING LINES'.

Appendices

A 12D Survey Guide

The information contained in this appendix outlines the general options, terminology, definitions and methods used by 12d Model for the purpose of the input, reduction and output of survey information. It is a general guide, with the appendices following relating to specific instruments and the interactions with 12d Model.

Please continue to the next section "Guide to Survey Reduction in 12d Model" .

Guide to Survey Reduction in 12d Model

The 12d Model survey options are used to reduce electronically recorded survey information and produce 12d Model strings, a process called **survey reduction**.

In the most general case, there are three steps involved:

1. 12d Model downloads raw data from a data collector and stores it on the computer.
2. The raw data file is converted to a standard 12d Model raw field file format, normally with extension of ".fld". For simplicity, the standard 12d Model raw field file is called the "12d field file".
3. The 12d field file is read into a 12d Model Survey Reduction function (12d Survey function) and reduced. If errors occur, the field data for 12d Survey function can be interactively and/or graphically edited. The reduction produces 12d Model super strings in one or many 12d Model models.

In some circumstances, not all steps are necessary.

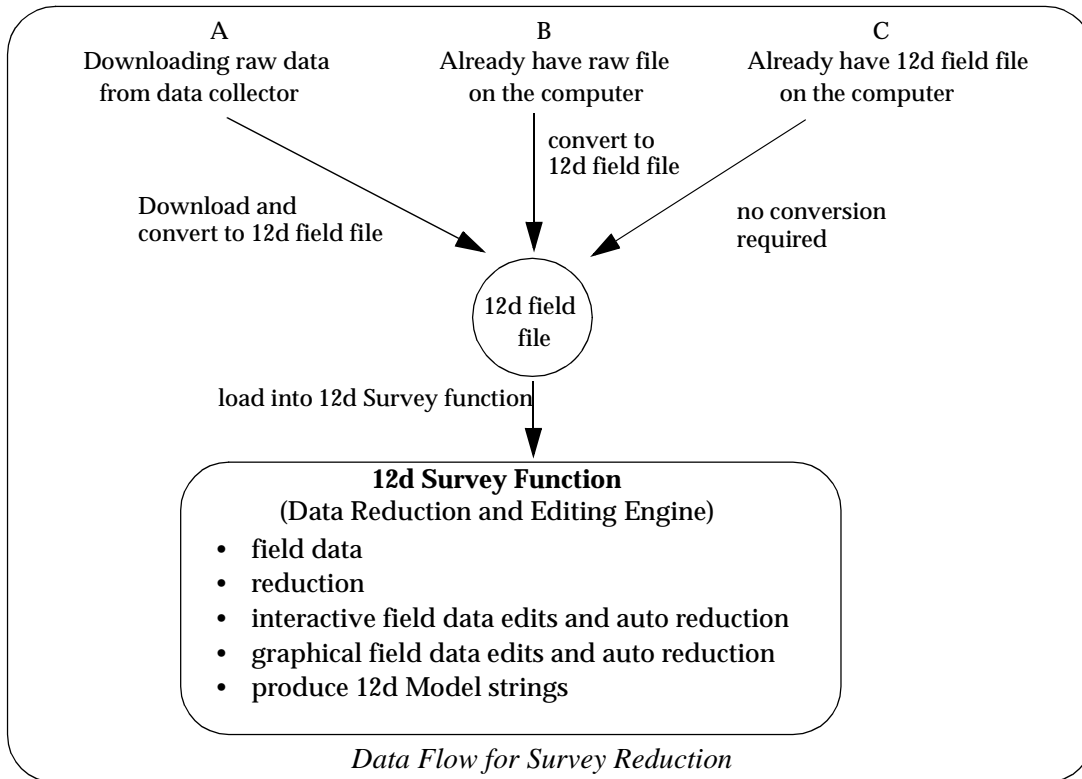

For example, Step 1 is not necessary when the raw data file is already on the computer (and hence doesn't need downloading).

This often occurs when data collectors have PCMCIA cards and PCMCIA card readers on the computer. Another example is when the raw data file has already been downloaded to the computer using another package such as HyperTerminal. Or maybe the raw data file has already been downloaded in a previous 12d Model session.

Steps 1 and 2 are not necessary when the data is already in the form of a 12d field file.

This occurs when other software packages, such as TP Setout, can produce a 12d field file. Or the 12d field file was created in a previous 12d Model session, maybe even on a different computer.

A data flow diagram for the survey reduction process is:

Please continue to the next section “Guide to Survey Coding in 12d Model” .

Guide to Survey Coding in 12d Model

At first the whole process may seem confusing because there are a multitude of methods of setting up coding in the field. Why isn't there just one way of doing things?

Firstly, each brand of survey instrument has a totally different format for recording information. Unfortunately there is no industry standard. In fact, different instruments from the same survey instrument manufacturer can have different formats for recording data.

Secondly, many of our customers were already familiar with another survey package and if possible, wished to continue field coding in the same way. Where possible, 12d Model has tried to accommodate this wish. Since 12d Model has replaced a number of survey packages, this led to yet more possible configurations.

12d Model has also been developing its own preferred method of field coding for each instrument. It is not compulsory to use the 12d method but of course it is the only way of taking advantage of features that are not available in other coding systems. For example, defining and using field templates and recording user-defined attributes on points and segments.

So to make help guide you through survey coding section:

- (a) There are field coding concepts used in 12d Model that are common to all instruments. For example, feature codes and string numbers, offset, close strings etc.
These are described in "Field Coding"
- (b) There are template field coding concepts used in 12d Model that are common to all instruments. These are described in "Field Templates"
- (c) There are shape field coding concepts used in 12d Model that are common to all instruments. These are described in "Shape field coding"
- (d) There are traverse field coding concepts used in 12d Model that are common to all instruments. These are described in "Traverse coding"
- (e) For leica instruments, the coding methods are different from most other types. These are described in "Field Coding for Leica Instruments"
- (f) For non-leica instruments, the concepts used in coding are similar for each type. These are described in "Field Coding for Non Leica Instruments"

Field Coding

EDM equipment is used to make readings of points in the field.

However, rather than just collecting points, it is usually desirable to add extra information by coding the readings in a way that can be interpreted during the data reduction process and produce more valuable information.

Unfortunately, there is no industry standard for this extra coding and it is software specific.

In 12d Model, the extra information is included in one or both of

- ▲ a *feature code* and *string number*
- ▲ extra commands called *field codes*

How the *feature codes*, *string number* and *field codes* are added in the field depends on the data collector being used and the coding convention set up by the user in 12d Model.

For example, some surveyors like to enter the *feature code* before the *string number*, others like to enter the *feature code* after the *string number*. Other surveyors don't use string numbers at all but prefer to use a *New String* command to start new strings (mainly ex SDR Map users).

In 12d Model, a particular *field coding convention* is defined by the user and stored with a **unique** name as a *data collector definition* in the file survey.4d. New data collector definitions can be created and existing ones modified using the *Survey Data Collectors* section of *Project=>Browse*.

12d Model converts all the raw data files from the different survey instruments and data recorders with different coding conventions, into the one 12d Model standard field file format before being loaded into a 12d Model Survey Reduction function and reduced. The 12d Model standard field file will simply be referred to as the 12d field file or just the field file.

The use of many of the commands allowed in the 12d field file will now be described. The complete definition of all the 12d field file commands will be described later.

The coding methodology for specific data recorders will be described in separate Sections.

Please continue to the next section "Stringing in the Field".

Stringing in the Field

In the coding convention, it is possible to specify that

- (a) *feature codes* and *string numbers* are used
- or
- (b) just *feature codes*.

Case (a) *feature codes* and *string numbers*

If *feature codes* and *string numbers* are entered with measurements in the field, a coding methodology is used so that strings are automatically created during the reduction process.

To allow this stringing, the **feature code** and **string number** are interpreted in the following manner:

During reduction, 12d Model connects measurement points with the **same feature code and string number** in the order they are measured in. That is, the feature code **and** string number determines which points are joined together to form the vertices of a super string. At the end of the reduction, the *string number* is dropped and just the *feature code* remains as the *name* for the super string.

Hence the *feature code* and *string number* combination allows any number of different super strings with the same name (feature code) to be produced.

If the *string number* is zero, then the point-line type of the super string is set to *point*. If the

string number is non-zero, the point-line type of the super string is set to *line*.

Finally, during reduction, the *feature code* can be used as the key to a mapping file to specify the name, model, colour, point-line type, linestyle, tinability and other details for the super string.

Note that the measurements of points with different feature codes and string numbers can be intertwined. That is, *not* all the points in one super string need to be measured before the points in a different super string.

Hence at the end of the reduction, 12d Model super strings are created for each unique *feature code* and *string number* combination in the input data.

Note - if the *string number* is blank, the *string number* defaults to 0

Case (b) just feature codes

If just *feature codes* are used then a *New String* command is used to start a new super string rather than giving a new string number.

During reduction, 12d Model connects measurement points with the **same** feature code in the order they are measured in until a *New String* command is found. That is, just the feature code determines which points are joined together to form a super string and the *New String* command defines when a new super string begins.

At the end of the reduction, the *feature code* remains as the *name* for the super string.

Also during reduction, the *feature code* can be used as the key to a mapping file to specify the name, model, colour, point-line type, linestyle, tinability and other details for the super string.

Note that the measurements of points with different feature codes can be intertwined. That is, *not* all the points in one super string need to be measured before the points in a different super string.

An Example of Coding to String Points Together

Two super strings are to be created, one joining points **a** and **c**, the other joining points **b** and **d**.

Points may be measured and assigned *feature codes* and *string numbers* as follows:

Measurement to point	Feature code	String Number
a	123	01
b	ABC	01
c	123	01
d	ABC	01

Alternatively, the points could have been measured in the order a, c, b, d as long as the correct

feature codes and string numbers were entered.

Measurement to point	Feature code	String Number
a	123	01
c	123	01
b	ABC	01
d	ABC	01

Because the *string numbers* are non-zero, the default *point-line* type for both super strings is *line*. Please continue to the next section “Offsets” .

Offsets

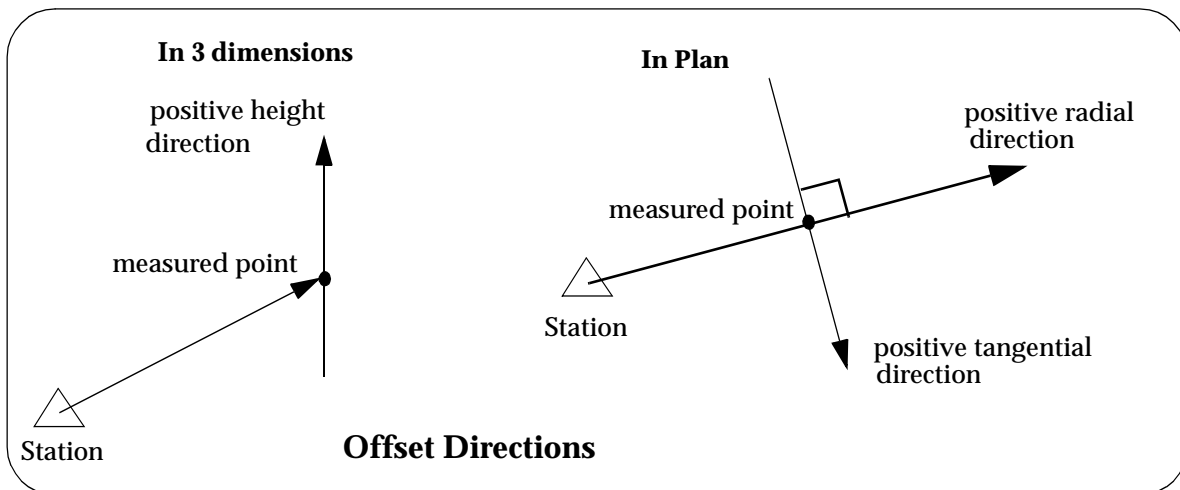

It is not always possible to measure a point directly but it may be possible to measure a point nearby and then measure an offset to adjust the measured point by and so produce the co-ordinates of the required point.

The three offsets that are allowed in the 12d field file are:

Height - The *height offset* adjusts the height of a non-null point. A positive offset adds to the height and a negative offset reduces the height.

Radial - The *radial offset* adjusts the position of the specified point by a *plan* distance from the specified points original position, along the plan line joining the current station to the specified point. A positive offset is away from the station and a negative offset is toward the station.

Tangential - The *tangential offset* adjusts the position of the specified point by a *plan* distance from the specified points original position, at rights angles to the plan line joining the current station to the specified point. A positive offset is to the right (looking from the station to the point) and a negative offset is to the left.

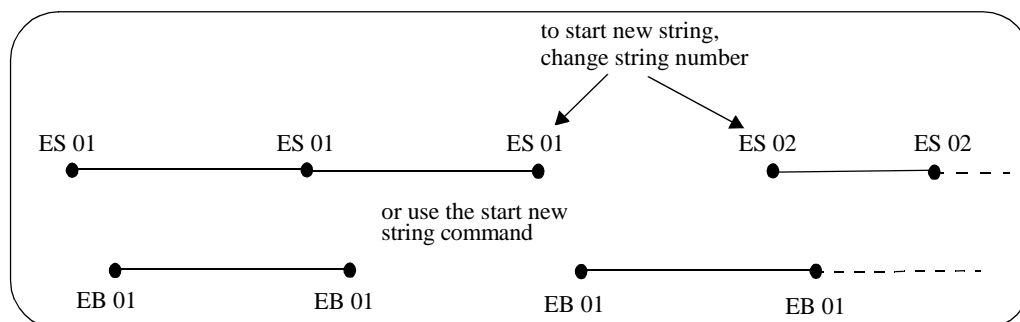

Please continue to the next section “Start New String” .

Start New String

A new string is automatically started whenever a different string number is used. However there is also a **start new string** command which begins a new super string even if the string number is the same as the string number for previous points.

The *New String* command is particularly useful for correcting the field error of forgetting to change the string number.

Please continue to the next section "Close String".

Close String

The close string command closes a super string by joining the first and last points of the super string. If a super string is already closed, then the close has no effect. The string closed command can be given at the recording of any point of the string, and the entire string is closed.

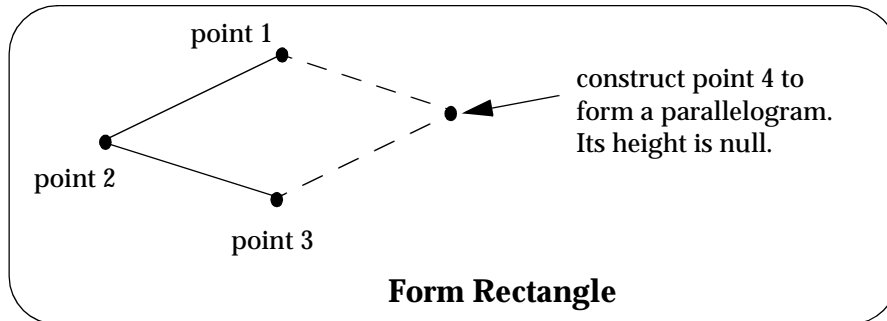

Please continue to the next section "Rectangle".

Rectangle

The rectangle command acts on last three points of a string and adds a new point after the last point to form a parallelogram (squashed rectangle). The string is then closed.

The height of the added point is set to null.

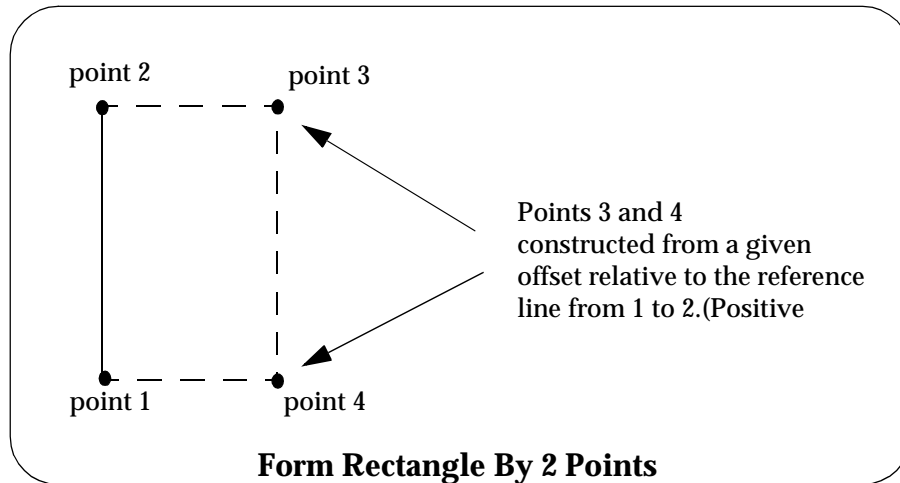

Please continue to the next section "Rectangle by 2 Points".

Rectangle by 2 Points

The rectangle by 2 pts command acts on last two points of a string and adds two new points at a given offset after the last point to form a rectangle. The string is then closed.

The height of the added points are set to null.

Please continue to the next section "Feature".

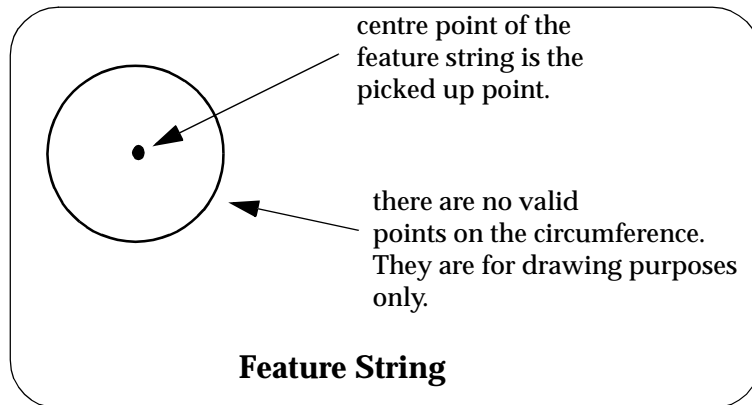

Feature

A *feature string* is a circle with a z-value at the centre but only null values on the circumference of the circle.

The feature commands creates a *feature string* with the picked up point as its centre and the radius/diameter being set by the feature command.

If a feature string is given a **world** line style, then the style is centred on the centre point of the feature string and scaled up to the radius of the feature string.

If a feature string is given a **screen** or **paper** line style, then the style is wrapped around the circumference of the feature string.

Please continue to the next section "Joining Strings" .

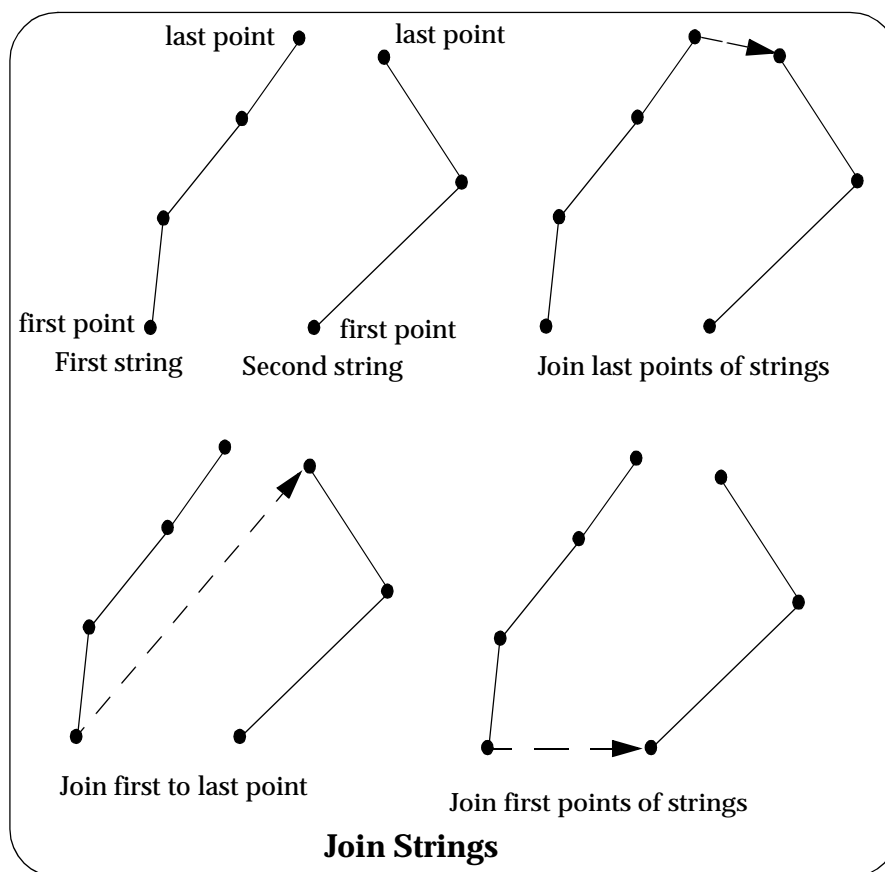

Joining Strings

There are three commands for joining two strings together.

Join last points of strings - the last point of the first string is joined to the last point of the second string. The direction of the final string is along the forward direction of the first string, across to the end of the second string and then in the reversed direction of the second string.

Join first to last points of strings - the first point of the first string is joined to the last point of the second string. The direction of the final string is in the reverse direction of the first string, across to the start of the second string and then in the forward direction of the second string.

Join first points of strings - the first point of the first string is joined to the first point of the second string. The direction of the final string is in the reverse direction of the first string, across to the start of the second string and then in the forward direction of the second string.

Please continue to the next section "Arcs Through Points".

Arcs Through Points

There are a number of commands to fit arcs through sequences of three or more points. Note that this is an **arc in plan**, with different z-values at each of the three points. The z-values are linearly interpolated around the arc between the points.

Hence it is a **helix** and **not** a circle in the plane containing the three points. Note that a 3d-arc in a plane not parallel to the x-y plane does **not** project onto an arc in the x-y plane.

There are arc commands to

- (a) fit an arc through the next three points
- (b) fit an arc through the previous three points.
- (c) fit arcs to sets of three points until stopped.

The first two cases need no explanation but in the final case, a arc is fitted to the first three points, and then another arc to points 3, 4 and 5 and then an arc through 5,6 and 7 and so on. If at any stage there is only one point left, then no arc can be fitted and a straight line is drawn to the final point.

Please continue to the next section "Field Templates".

Field Templates

If a series of points are being picked up along the one string then the *feature code* and *string number* only need to be entered once since the default for a measurement is to use the last *feature code* and *string number* if no new ones are given. However it is often much more efficient to pick up one point from a number of strings before moving onto the next point of the each string (cross section pick up).

For example when picking up a road, it would be preferable to pick up the points for a section across the road and then move onto the next section rather than picking up all of one string at a time. In the diagram below, this means picking up one point from each of the strings LV, LS, LK, CL, RK, RS, RV and then moving onto the next cross section rather than picking up all of LV and then all of LS and so on.

Normally if each measurement is from a different string, then the feature code and string number would need to be re-entered with each measurement which is a very time consuming process. To simplify the coding for section pick up, 12d Model uses *field templates*.

Basically, a 12d Model *field template* consists of defining a sequence of *feature codes* and *string numbers* for the field template. The field template can be given a unique name or have no name at all.

When a field template is used, measurements are taken without entering a *feature code* and *string number* and the *feature code* and *string number* for the measurement come from the *field template definition*.

For example, a field template could be defined as the sequence:

LV 01, LS 01, LK 01, CL 01, RK 01, RS 01, RV 01

When the field template is used, measurements are taken without giving a feature code or string number and the measurements will be sequentially given the codes LV 01, LS 01, LK 01 etc.

To define a 12d Model *field template*, there is a command to *start recording* the field template. The *feature codes* and *string numbers* for the next series of measurements until the *stop recording* command is given, are stored as the field template. There are also commands to *insert* and *delete* a point in the template when picking up.

When a field template is used, the feature code and string number from the field template can be used:

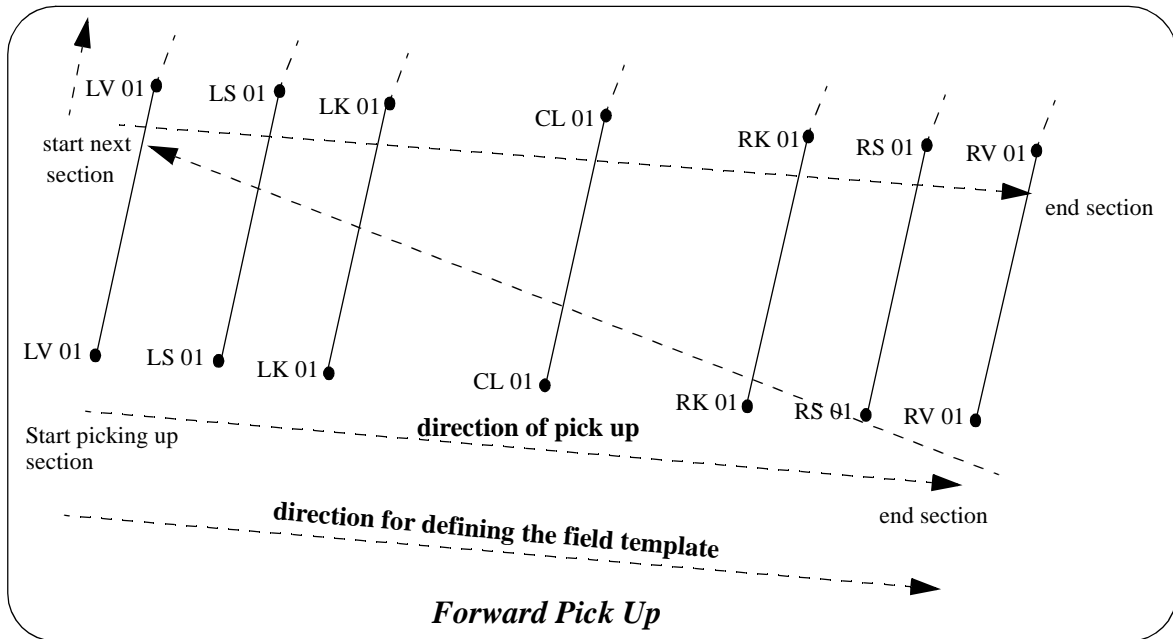

- in the same order as the codes are defined in the field template (forward direction).
- in the opposite order to how the codes are defined in the field template (reverse direction).
- in an alternating same and opposite order that the codes are defined in field template (zig-zag)

These three modes of usage of a field template will be described in the following sections.

Please continue to the next section "Forward Direction".

Forward Direction

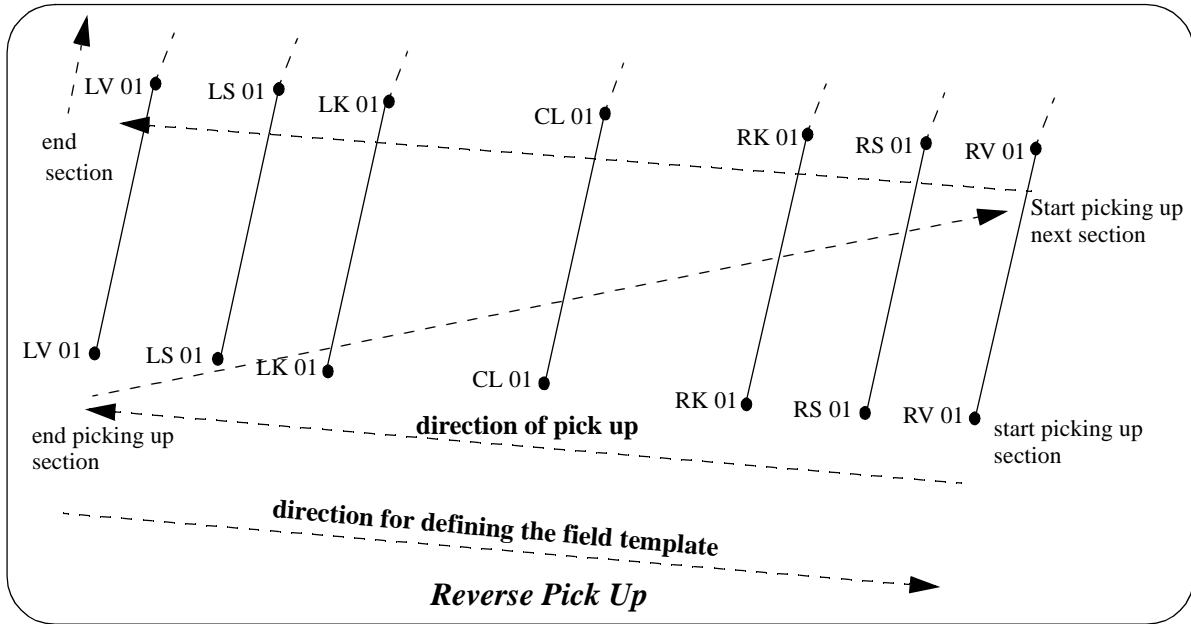

If the field template is used in the *forward* direction, then the feature codes and string numbers are used in the same order that they were defined to be in the field template. Once the end of the field template is reached, the feature codes and string numbers re-start at the beginning of the field template.

Please continue to the next section “Reverse Direction” .

Reverse Direction

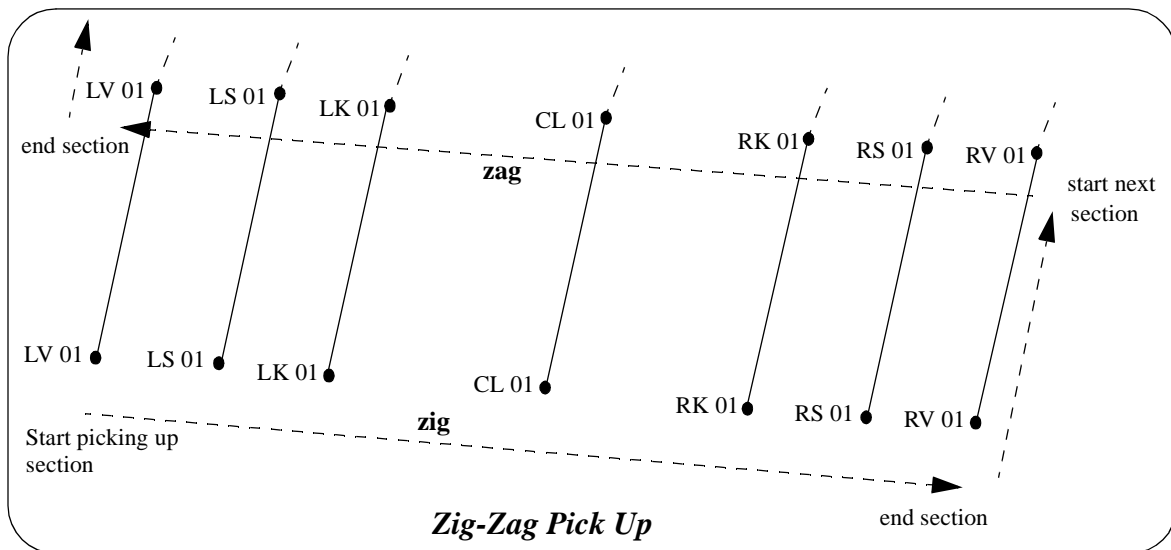

If the field template is used in the *reverse* direction, then the feature codes and string numbers are used in the reverse order to what they were defined to be in the field template. That is the feature codes and string numbers start at the *end* of the field template definition and are used in the reverse order. Once the beginning of the field template is reached, the feature codes and string numbers re-start at the end of the field template and are used in the reverse order.

Please continue to the next section "Zig-Zag".

Zig-Zag

When picking up a road in sections, it is often quickest to pick up the first section going from one side of the road to the other side, and then move onto to the next section point on the other side of the road and pick up points coming back across the road. Hence the points for the second section are in the reverse order to those in the first section. This process is known as zig-zagging.

This situation can be covered in two ways. A field template could be defined containing all the points for two sections and the field template used in the forward (or reverse) direction. For example, the field template to be used in the forward mode could be defined as:

LV 01, LS 01 LK 01, CL 01, RK 01, RS 01, RV 01, RV 01, RS 01, RK 01, CL 01, LK 01, LS 01, LV 01

However, in 12d Model it is only necessary to define the *one* section

LV 01, LS 01 LK 01, CL 01, RK 01, RS 01, RV 01

and when the field template is used, it is specified that it is being used as a *zig-zag* field template starting on either the *zig* (the forward direction of the field template) or the *zag* (the reverse direction of the field template).

Once a *zig* is completed, 12d Model automatically uses the reverse order of the field template and hence produces a *zag*. Similar, once a *zag* is completed, 12d Model uses the forward order of the field template and produces a *zig*.

Thus a *zag* automatically follows a *zig* and a *zig* follows a *zag*.

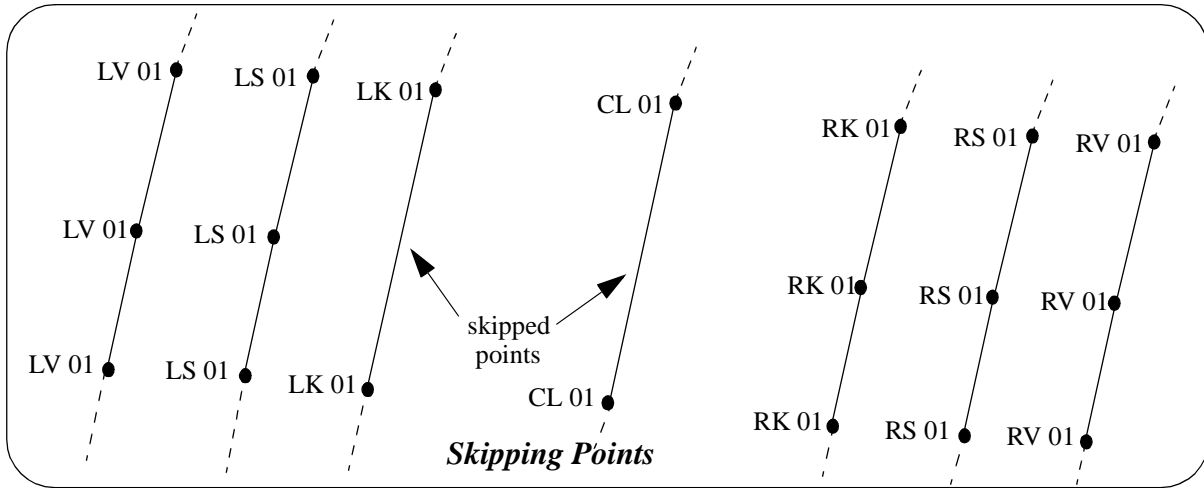

Hence if a field template is used in the *zig-zag* mode, it can be used as either:

- (a) a *zig-zag* field template starting on the *zig*
- (b) a *zig-zag* field template starting on the *zag*.

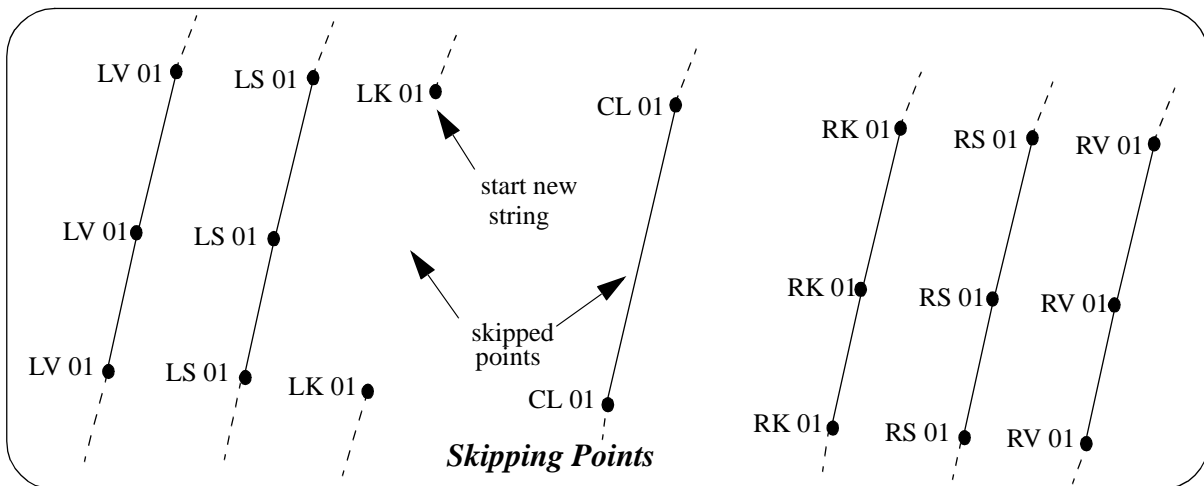

Please continue to the next section “Skipping Field Template Points” .

Skipping Field Template Points

When picking up points using a field template, 12d Model allows for one or more points to be skipped. By default, the points on the strings on either side of the skipped points will then be joined together.

By combining skipping points and start new string commands, points can be skipped and new strings started on the other side of the skipped points.

Please continue to the next section "Insert Template Points" .

Insert Template Points

When picking up points using a field template, 12d Model allows for one or more points to be inserted. The inserted points change the template from that point onwards so that extra strings can be picked up as they arise.

If the insert point command is given after the last point of a template, a flag should also be applied to specify which template pick-up the inserted point is to be added. i.e. The last series of points or the next series. This flag is called the "insert special" flag. If ticked on the insert panel or if the flag given in the offset code is 1, the point will be added to the current pick-up template. In the case shown below, the insert special flag should be set to on so that the next picked up point will be on the current template. The insert would have been made after the last LV 01 observation in the last pick-up direction. The following pick-up will use the redefined template definition.

It is also possible to multiple code points such that more than one code can be assigned to the one pick-up point. In the case shown below, an insert was made on the next pick-up direction after the LV 01 observation. The multiple code tick box or flag was set on so that the last picked up point will be assigned the extra code specified, in this case DR 01. The template will be applied to all subsequent measurements such that the observed LV_01 string will also be coded DR 01.

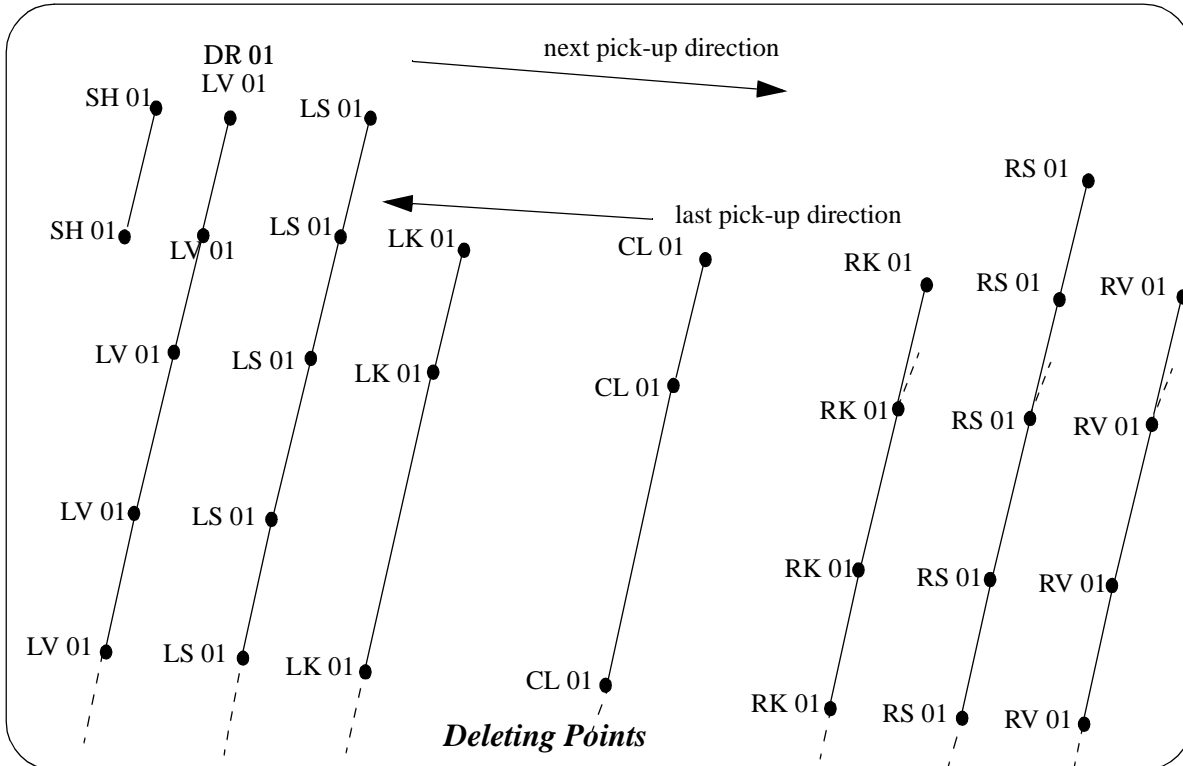

Please continue to the next section "Delete Template Points" .

Delete Template Points

When picking up points using a field template, 12d Model allows for one or more points to be deleted. The deleted points change the template from the next specified number of points inclusive of the current point. i.e. They are removed from the template.

If a template delete command was given after the LS 01 string in the next pick-up direction, and the number of specified points were 3, the template will be altered such that the next observed string will be RS 01.

Shape field coding

If an object of a standard section is to be picked up such as a length of kerb, a shape can be defined and extruded/paralleled along a single pick-up string related to that shape.

For example, a kerb shape can be defined by observing all points on a typical section of the kerb and assigned a shape name. Then when picking up the length of kerb, only one reference string to the shape (defined when recording the shape) has to be picked up e.g. lip of kerb. On reduction, 12d can extrude or parallel the shape such that the strings/shape of the kerb are produced for the entire kerb pick-up.

Normally if each measurement is from a different string e.g. back of kerb, lip kerb etc., then the feature code and string number would need to be re-entered with each measurement which is a very time consuming process. To simplify the coding for section pick up, 12d Model uses *shape field coding*.

Basically, a 12d Model *shape* consists of observing a number of points on a given section of an object. The shape can be given a unique name or have no name at all.

For example, a shape can be defined by observations shown in order above

1- being the reference point, 2- 7 being the shape points. In this case, the 1st point of the shape pick-up coincides with the reference point.

To define a 12d Model *shape*, there is a command to *start and end the recording* of the shape. The *feature codes* and *string numbers* for the next series of measurements until the *stop recording* command is given, are stored in the final shape.

As the shape is defined, other field codes can be used in conjunction such as offset. In this example an observation may be made at 5 for the position of 6 using a vertical offset. Similarly for point 7 using the observation at a point near point 2. In addition, points 6 and 7 can be made non-tinable so that formation of a tin is constrained to the surface of the kerb.

The next step is to pick up the entire length of the kerb at the reference string position using the same *feature code* and *string number* used for the reference string in the shape pick-up. In this example the lip of kerb.

Once completed, the shape can be extruded or paralleled using the extrude or parallel

commands. The parallel command will create a number of strings according to the number of points on the shape. The extrude will create a super string with a shape defined like a pipe string.

Traverse coding

If a traverse is undertaken as part of a survey, a traverse code and string number can be coded so that 12d can extract the traverse information. The specific traverse code can be supplied in the survey reduction panel under the traverse tab. An example is shown below:

Traverse	Geodetics	Others
Do traverse calcs		<input checked="" type="checkbox"/>
Traverse code	TL	+
Adjust method		▼
Network model	traverse string	

In this case, the feature code of TL will be searched in the field file on reduction, so that a traverse string can be extracted. The user is required to nominate the foresight measurement with the TL code in this example. If they also include the TL code in a backsight to a previously defined traverse leg, a reciprocal calculation will be made. It uses the pair of observations (Foresight and Backsight observations of the same line e.g. Foresight 1001 to 1002 and backsight from 1002 to 1001). This reciprocal calculation takes the mean of the distance and vertical angles eliminating the effects of refraction.

A number of separate but interrelated traverses can be extracted using differing string numbers in the field.

The traverse code also allows for adjustments to be made between known stations. This adjustment maybe be chosen in the reduction panel. This field is optional.

Field Coding for Leica Instruments

For Leica instruments, the Leica GSI format breaks lines of data into fixed length 'words' and cannot use the same encoding method as the other instruments. The 12d Model coding system for the Leica TPS instruments is covered in the section "12D and Leica TPS Instruments" .

Field Coding for Non Leica Instruments

EDM equipment is used to make readings of points in the field.

Rather than just collecting points, it is usually desirable to add extra information by coding the readings in a way that can be interpreted during the data reduction process and produce more valuable information. Unfortunately, this extra coding is non-standard and software specific.

In 12d Model, all the raw data files from different data collectors are converted into the one standard field file format (the 12d Model field file) before being loaded into a 12d Model Survey Reduction function and reduced. Hence the method for coding information in the data collector in the field needs to be well defined so that it can be sensibly converted into a 12d Model field file (the section "The 12d Field File Format" contains the complete description of the 12d field file).

When a measurement is taken, most data collectors (Sokkia, Geodimeter, Topcon, Nikon etc.) allow the user to enter text which is then output with the measurement data. Depending on the data collector, the total number of characters of text may be strictly limited and may also be restricted to only one line of text. In 12d Model, a coding system has evolved so the text can be interpreted in a meaningful way.

Blocks and the Block (Command) Delimiter

To allow the one line of text to hold a variety of different information, the line of text is broken up into smaller blocks and each block is processed separately.

The character (or characters) used as the block separator is called the *command delimiter* or *block delimiter*.

Obviously the command delimiter can not appear in any of the commands inside a block.

What is used for the *command delimiter* is user defined in the data collector definition and is found on the *Delimiters* tab of the *Survey.4d Create/Edit* panel in the section "Data Collector Definitions".

The default command delimiter is * and this will be used in the examples in this appendix.

Hence using the command delimiter, the text line is broken into separate blocks for processing.

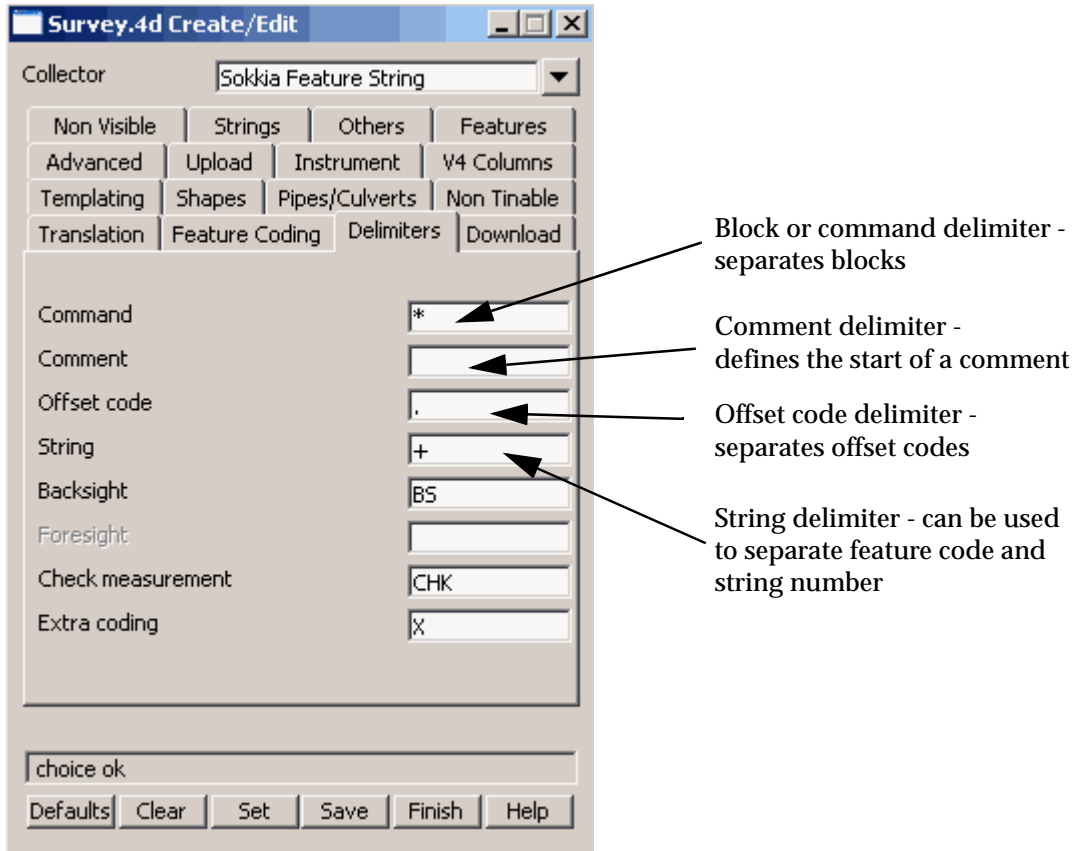

For example, the text string

EB01*XA.road

breaks into the separate blocks.

EB01

XA.road

A block can be either a **control code block** or a **feature code block**.

A **control code block** is any block that start with a valid **control code**.

Valid control codes are simply the one or more characters of text designated in the *Delimiters*, *Features*, *Templating*, *Pipes/Culverts*, *Not Tinable* and *Strings* tabs in the **Survey.4d Create/Edit** panel for the selected data collector definition.

If no control code appears at the start of the block, then the block is taken to be a **feature code block**.

For example, for the *Sokkia Feature String* data collector definition which is installed with 12d Model, the **valid control codes** are *, dot (.), space, +, BS, CHK, X, C, R, S, E, ST, XA, XB, XC, XD, XE, XF, NH, XP, XL, XN, I, O and A

Any block starting with any of above control codes is a **control code block**. Blocks that aren't control code blocks are **feature code blocks**.

Translation	Feature Coding	Delimiters	Download	Non Visible	Strings	Others	Features

Tabs on the *Sokkia Feature String* data collector definition which define Control Codes

Blocks can include *comments* and how a comment is specified is given in the next section “Comments in a Block” .

The feature code block is discussed in the section “Feature Code Blocks” .

The explanation of each control code is given in the section “Control Code Blocks” .

Please continue to the next section “Comments in a Block” .

Comments in a Block

Comments are supported in a block. There is a *Comment* delimiter and all characters after the *comment* delimiter to the **end** of the **block** are treated as a comment.

Comments are attached to the measurement point as **text**.

Hence the *measurement* will create a vertex on a super string and the *comment* will create text at that vertex of the super string.

The default for the *Comment* delimiter is / and it is defined by the *Comment* field on the *Delimiters* tab of the *Survey.4d Create/Edit* panel.

For example, if * is the command (block) delimiter and / is the comment delimiter, then in

EB01/first point of a template*XA.road

there are two blocks *EB01/first point of a template* and *XA.road*

and the text "first point of a template" in the first block is a comment and will be added to the super string as vertex text.

Another common character to use as a *comment delimiter* is a space (' '). For example, if * is the command delimiter and space is the comment delimiter, then in

EB01 first point of a template*XA.road

"first point of a template" is a comment.

The *comment* delimiter for the *Sokkia Feature String* data collector is a space

Please continue to the next section "Feature Code Blocks" .

Feature Code Blocks

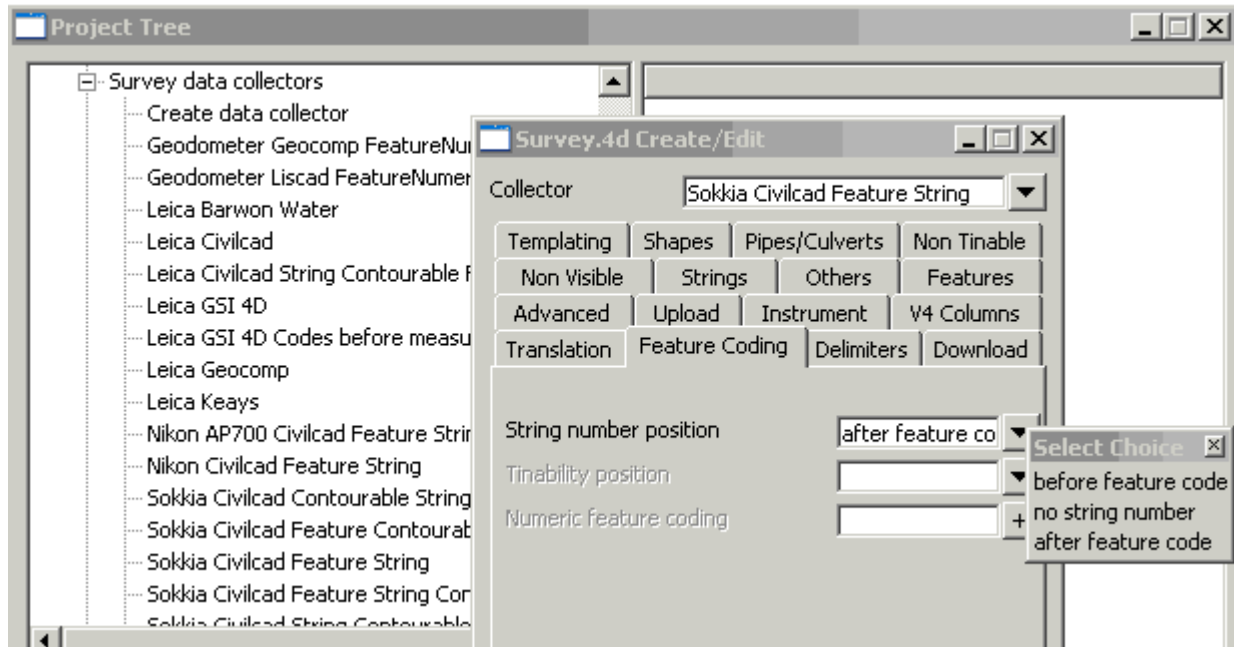

Feature Code, String Number and String Delimiter

In a feature code block, the *feature codes* and *string numbers* are given so that strings are automatically created during the reduction process.

The *feature code* and *string number* appear at the start of the feature code block and can be entered in a variety of ways.

Some surveyors like to enter the *string number* before the *feature code* and other surveyors prefer to enter the *string number after the feature code*. Some surveyors prefer to use *no string numbers* at all (SDRmap users) and use a *new string* control code to start a new string.

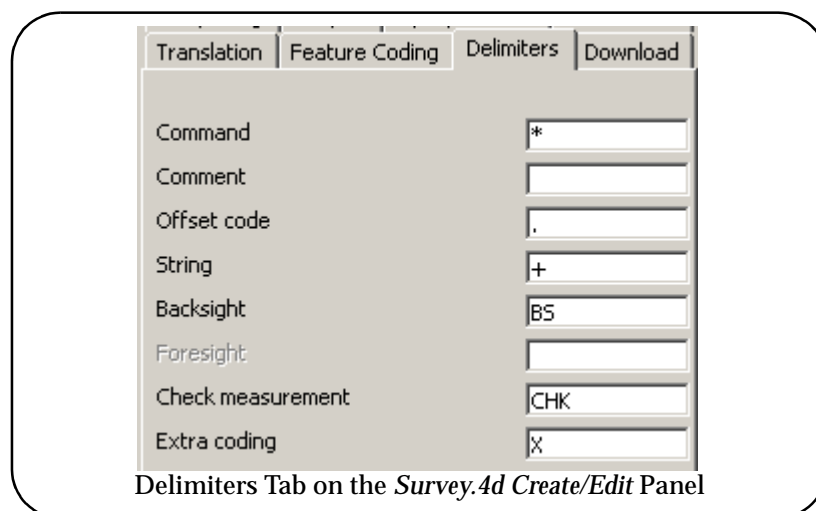

All three methods are supported in 12d. The setting is made on the *String number position* field on the *Feature Coding* tab of the *Survey.4d Create/Edit* panel. The default is 'before feature code'.

If string numbers are going to be used (either *before feature code* or *after feature code*) then there are rules for determining what is the feature code and what is the string number. Note that the *string number* is always *numeric* and can be any length.

Firstly, the *feature code* and *string numbers* can be separated by an **optional String** delimiter given by the *String* field on the *Delimiters* tab of the *Survey.4d Create/Edit* panel. The default character for the *string delimiter* is +.

For example, 20+110KVA is interpreted as string number '20' and feature code '110KVA' if the string number comes before the feature code.

If a String delimiter is not used, then there are **some restrictions** on the feature code so that the feature code and string number can be split apart. Note that the *string number* is always *numeric* and can be any length.

If a string delimiter is not used, then either

- (a) the *feature code* must be *purely alpha* and then the feature code can be of any length.

or

- (b) the *feature code* is purely numeric. Then the feature code must be the **fixed length** given by the *Numeric feature coding* field on the *Feature Coding* tab of the *Survey.4d Create/Edit* panel. If the *Numeric feature coding* field is not set and the feature code is numeric, then the whole thing is interpreted as a feature code with a string number of 0.

If a *feature code* is a **mixture of alpha and numeric**, then a **string delimiter must be used** to separate the feature code from the string number. Once a string delimiter is used, feature code can be any length.

Tinability as Part of the String Number

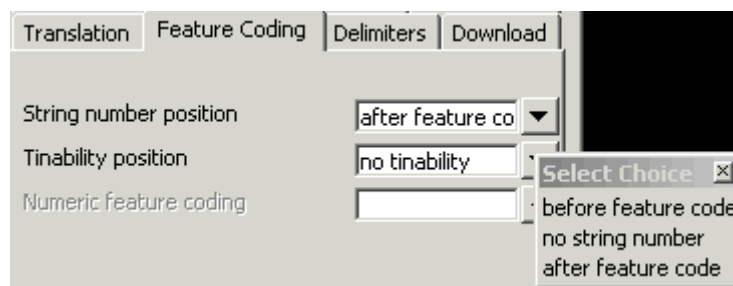

For compatibility with other software coding schemes, the tinability of a point can be included as part of the string number. This is **not normally recommended** since 12d has more flexible methods of defining tinability.

The field *Tinability position* on the *Feature Coding* tab of the *Survey.4d Create/Edit* panel controls whether it is used or not. The default is 'no tinability' as part of the string number.

If tinability is used as part of the string number, then it consists of either a **0** or a **1**.

If *Tinability position* is set to *before string*, the first character of the *string number* is stripped off and taken as the tinability flag. A value of 1 means the point is tinable and 0 is non-tinable.

If *Tinability position* is set to *after string*, the last character of the *string number* is stripped off and taken as the tinability flag. A value of 1 means the point is tinable and 0 is non-tinable.

Offset Codes

It is not always possible to measure a point directly but it may be possible to measure a point nearby and then measure an offset to adjust the measured point by and so produce the coordinates of the required point. The three offsets that are allowed in 12d Model are height, radial and tangential. See the Section "Offsets" for more information.

The three offsets height, radial and tangential have the codes H, R and T respectively.

The *offset codes* come after the feature code-string number combination and are separated by the **Offset code** delimiter whose default value is a decimal point (.) and is defined by the *Offset code* field on the *Delimiters* tab of the *Survey.4d Create/Edit* panel.

After the *offset code delimiter*, the offset code is given as either H, R or T and then a real value for the offset (with no spaces in between). The offset can be positive or negative with the sign only being recorded if negative. A second and third offset code (H, R or T) can follow the first but no offset code delimiter is used for the second or third offset codes. The offset code delimiter is only used to separate the field code-point number from the offset codes.

In the example 20+110KVA.H2.1T0.5 there is a horizontal offset of 2.1 and a tangential offset of 0.5.

Multiply Coded Points

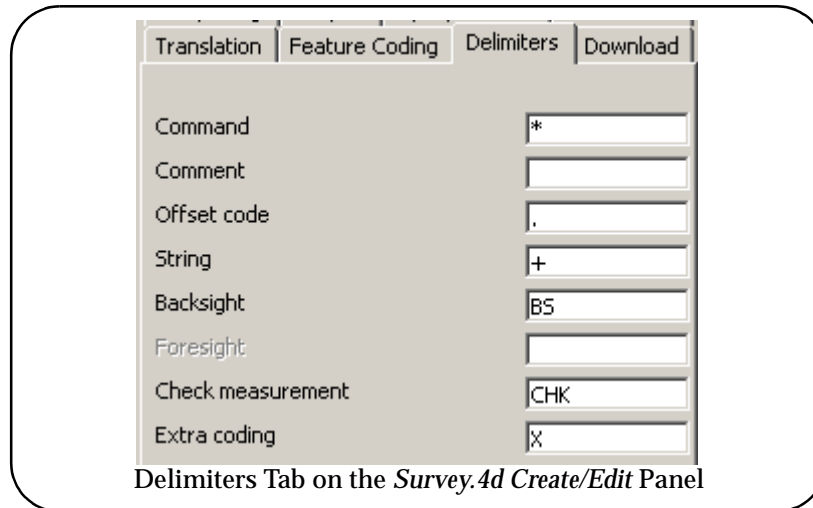

It is possible to have more than one *Feature code block* and this will create a multiply coded point.

For example, if the command delimiter is *, then EB01*PP would have the two feature code blocks 'EB01' and 'PP'.

Please continue to the next section "Control Code Blocks".

Control Code Blocks

Control Codes on the Delimiters tab

Extra Coding

This code is only for the instruments supporting the Sokkia SDR format.

The default for the *extra coding* control code is **X** and it is defined by the *Extra coding* field on the *Delimiters* tab of the *Survey.4d Create/Edit* panel.

For some instruments, extra lines of information can be entered after a measurement. For example on a Sokkia by using the note (13NM) to add more information to the previous measurement line (07).

The *extra coding* control code is used to append this additional information to the information on the measurement line. Hence it is then possible to have extra blocks of information on the line (or lines) following the measurement line.

The block containing the *extra coding* control code must be the last block on the measurement line.

For example,

```
EB01/first point of a template*XA.road*X
/ this is some extra info that happens to be a comment
```

is the same as

```
EB01/first point of a template*XA.road*/ this is some extra info that happens to be a comment
```

Note that there must be a feature code block on the measurement line otherwise a point will be created with no name.

Backsight

The default for the *backsight* control code is **BS** and it is defined by the *Backsight* field on the *Delimiters* tab of the *Survey.4d Create/Edit* panel.

The rest of the block after the *backsight control code* is the name of the station that the backsight was to, or the point number that the backsight was to.

For example, if *BS* is the backsight control code

```
BSPSM3
```

would designate a backsight to the station PSM3.

If only the backsight control code exists, the point number from the reading is taken as the point number for the backsight. This may be data collector dependent.

Warning for feature codes starting with the *backsight* control code.

If the feature codes comes before the string number, then feature codes for ordinary measurements **can not** start with the backsight control code because they would be interpreted as backsight measurements and no measurement point would be created.

If the feature codes comes after the string number, then whenever a feature codes for ordinary measurements is used that starts with the backsight control code, a string number (which may be zero for a point string) **must** be used otherwise the feature code will be interpreted as a backsight measurement and no measurement point would be created.

Foresight

There is no default for the *foresight* control code. It is defined by the *Foresight* field on the *Delimiters* tab of the *Survey.4d Create/Edit* panel.

The rest of the block after the *foresight control code* is the name of the station that the foresight was to, or the point number that the foresight was to.

For example, if *FS* is the backsight control code

FSPSM3

would designate a backsight to the station PSM3.

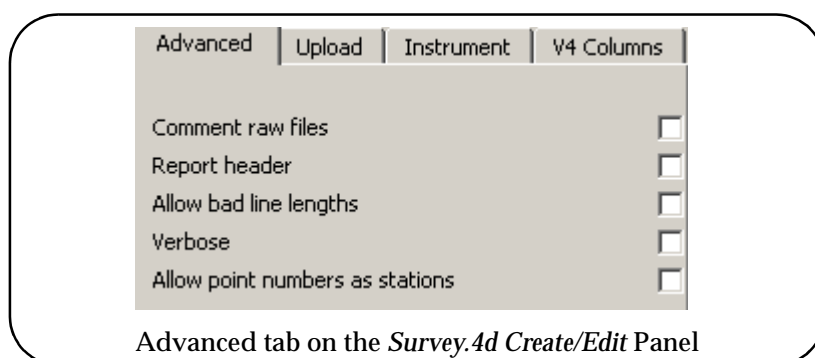

If only the foresight control code exists, the point number from the reading is taken as the point number for the foresight. This may be data collector dependent.

Warning for feature codes starting with the *foresight* control code if the *Allow point numbers as stations* flag is *not set* on the *Advanced* tab of the *Survey.4d Create/Edit* panel.

If the feature codes comes before the string number, then feature codes for ordinary measurements **can not** start with the foresight control code because they would be interpreted as foresight measurements and no measurement point would be created.

If the feature codes comes after the string number, then whenever a feature codes for ordinary measurements is used that starts with the check measurement control code, a string number (which may be zero for a point string) must be used otherwise the feature code will be interpreted as a foresight measurement.

If the *Allow point numbers as stations* flag is set on, then a point number used as a foresight will create a measurement point for that point number.

Check Measurement

The default for the *check measurement* control code is **CHK** and it is defined by the *Check measurement* field on the *Delimiters* tab of the *Survey.4d Create/Edit* panel.

The rest of the block after the *check measurement control code* is the name of the station that the

check measurement was to, or the point number that the check measurement was to.

For example, if *CHK* is the check measurement control code

CHKPSM3

would designate a check measurement to the station PSM3.

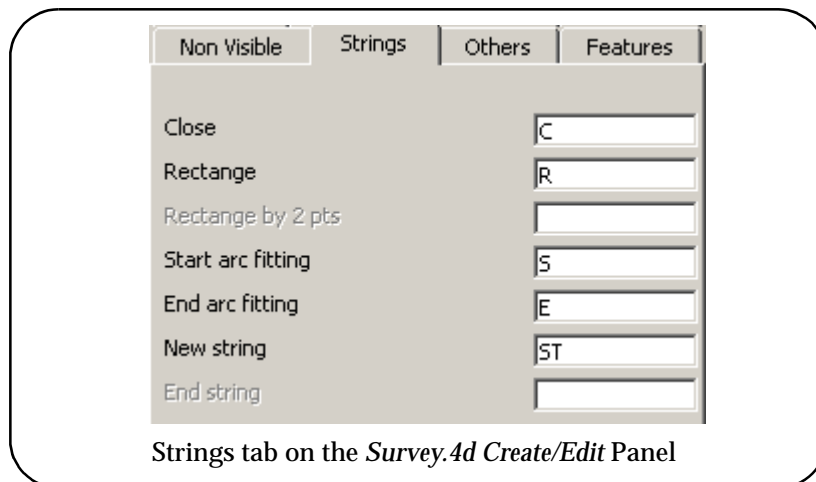

If only the check measurement control code exists, the point number from the reading is taken as the point number that the check measurement is made to. This may be data collector dependent.

Warning for feature codes starting with the *check measurement* control code.

If the feature codes comes before the string number, then feature codes for ordinary measurements **can not** start with the check measurement control code because they would be interpreted as check measurements and no measurement point would be created.

If the feature codes comes after the string number, then whenever a feature codes for ordinary measurements is used that starts with the check measurement control code, a string number (which may be zero for a point string) **must** be used otherwise the feature code will be interpreted as a check measurement and no measurement point would be created.

Control Codes on the Strings tab

Close String

The default for the *close string* control code is **C** and it is defined by the *Close* field on the *Strings* tab of the *Survey.4d Create/Edit* panel.

The *close string* control code closes the string that the measurement is a point of.

See the Section “Close String” for more information on closing a string.

Rectangle

The default for the *rectangle* control code is **R** and it is defined by the *Rectangle* field on the *Strings* tab of the *Survey.4d Create/Edit* panel.

The *rectangle* control code uses the current point and the previous two points in the same string (three points total) and creates a new point to form a parallelogram.

See the Section “Rectangle” for more information on forming a rectangle.

Rectangle by 2 Pts

A *rectangle_2* control code can be defined by the *Rectangle by 2 pts* field on the *Strings* tab of the *Survey.4d Create/Edit* panel.

The *rectangle_2* control code uses the current point, last point and an offset. The rectangle is

defined by two points (reference side) and a offset.

If a positive offset value is given, two points will be created to the right of the reference side.

If a negative offset value is given, two points will be created to the left of the reference side.

If no Description is given, the two new points will be joined to the given points in a closed rectangular string, and will have the same feature code as the points given.

If the feature code and string number exist, then a search is made for the last occurrence of two points with the same feature code and string number. If found, then these points are used to define the reference side of the rectangle.

If the point number exists, then a search is made for the last occurrence of two points with the same feature code and string number as the point given by the point number. If found, then these points are used to define the reference side of the rectangle.

Two consecutive rectangles are unable to be defined side by side. In other words if the two points given are part of string of greater than two vertices, the command will only work for sets of two points that are exclusively defined. i.e. For a 5 point string, a rectangle can be defined by points 1 and 2, and 4 and 5.

See the Section “Rectangle by 2 Points” for more information on forming a rectangle by 2 points.

Start Arc Fitting

The default for the *start arc fitting* control code is **S** and it is defined by the *Start arc fitting* field on the *Strings* tab of the *Survey.4d Create/Edit* panel.

The *start arc fitting* control code starts arc fitting with the current point.

See the Section “Arcs Through Points” for more information on arc fitting.

End Arc Fitting

The default for the *end arc fitting* control code is **E** and it is defined by the *End arc fitting* field on the *Strings* tab of the *Survey.4d Create/Edit* panel.

The *end arc fitting* control code ends arc fitting at the current point. That is, the current point is included in the arc fitting but it is the last point used in the arc fitting.

See the Section “Arcs Through Points” for more information on arc fitting.

New String

The default for the *new string* control code is **ST** and it is defined by the *New string* field on the *Strings* tab of the *Survey.4d Create/Edit* panel.

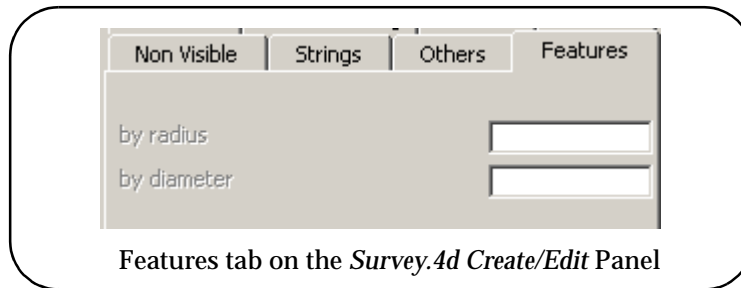

The *new string* control code starts a new string with the current point even if the feature code and string number haven't changed.

See the Section “Start New String” for more information on starting a new string.

End String

The *end string* control code ends the current string even if the feature code and string number haven't changed for the next point.

Control Codes on the Features tab

Feature by Radius

There is no default for the *feature by radius* control code. It is defined by the *by radius* field on the *Features* tab of the *Survey.4d Create/Edit* panel.

The *feature by radius* control code denotes that the feature has a given radius. For example, if RA was used then TRE*RA2 would denote a feature code TRE with a radius of 2 units.

See the Section “Feature” for more information on feature strings.

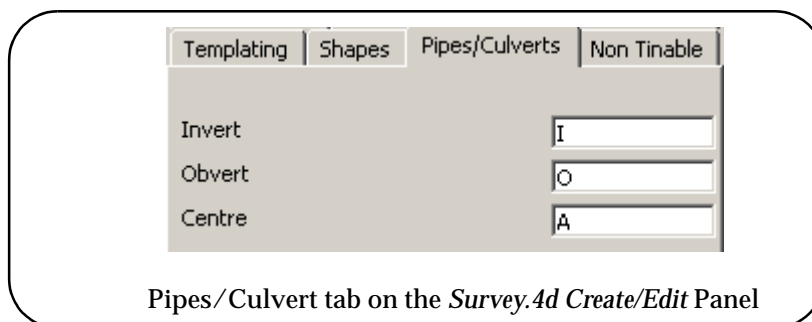

Feature by Diameter

There is no default for the *feature by diameter* control code. It is defined by the *by diameter* field on the *Features* tab of the *Survey.4d Create/Edit* panel.

The *feature by diameter* control code denotes that the feature has a given diameter. For example, if DI was used then TRE*DI2 would denote a feature code TRE with a diameter of 2 units.

See the Section “Feature” for more information on feature strings.

Control Codes on the Pipes/Culverts tab

Invert Point for Pipe or Culvert

The default for the *invert level* control code is I and it is defined by the *Invert* field on the *Pipe/Culverts* tab of the *Survey.4d Create/Edit* panel.

The *invert level* control code denotes that the point is an invert level (bottom).

The invert commands can also denote the diameter of a pipe or width and height of a culvert. For example, I.3 denotes the measurement was an invert level and it was a pipe of diameter 0.3 units. I.3x.4 denotes the measurement was an invert level and it was a box culvert of width 0.3 and height 0.4 units.

Obvert Point for Pipe or Culvert

The default for the *obvert level* control code is O and it is defined by the *Obvert* field on the *Pipe/Culverts* tab of the *Survey.4d Create/Edit* panel.

The *obvert level* control code denotes that point is an obvert level (top).

The obvert command can also define the diameter of a pipe or width and height of a culvert. For example, O.3 denotes the measurement was an invert level and it was a pipe of diameter 0.3 units. O.3x.4 denotes the measurement was an invert level and it was a box culvert of width 0.3 and height 0.4 units.

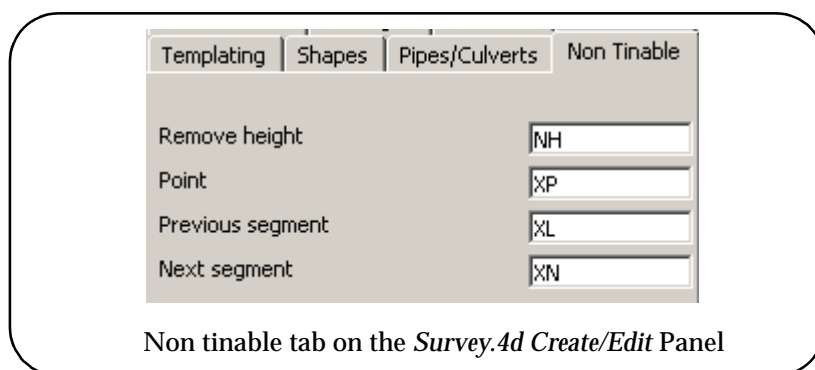

Centre Point for Pipe or Culvert

The default for the *centre level* control code is **A** and it is defined by the *Centre* field on the *Pipe/Culverts* tab of the *Survey.4d Create/Edit* panel.

The *centre level* control code denotes that point is an centre level (axial).

The centre command can also define the diameter of a pipe or width and height of a culvert. For example, A.3 denotes the measurement was an invert level and it was a pipe of diameter 0.3 units. A.3x.4 denotes the measurement was an invert level and it was a box culvert of width 0.3 and height 0.4 units.

Control Codes on the Non Tinable tab

Remove Height

The control code to set the height of the current point to null.

The default for the *remove height from point* control code is **NH** and it is defined by the *Remove height* field on the *Non-Tinable* tab of the *Survey.4d Create/Edit* panel.

Point

The default for the *make point non-tinable* control code is **XP** and it is defined by the *Point* field on the *Non-Tinable* tab of the *Survey.4d Create/Edit* panel.

The *make point non-tinable* control code makes the current point non-tinable. That is, the point is not used in tins (triangulations).

Previous Segment

The default for the *make previous segment non-tinable* control code is **XL** and it is defined by the *Previous segment* field on the *Non-Tinable* tab of the *Survey.4d Create/Edit* panel.

The *make previous segment non-tinable* control code makes the previous segment non-tinable. That is, the segment that the current point is the end of is non-tinable and hence not used as a breakline in tins (triangulations).

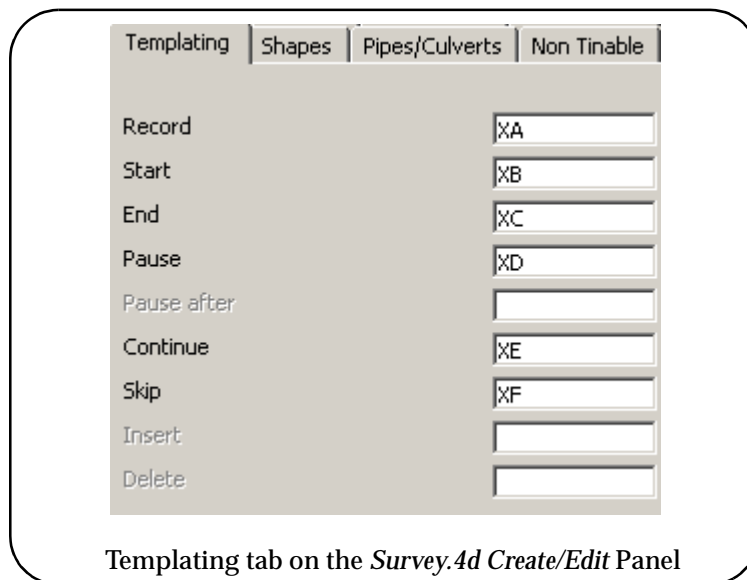

Next Segment

The default for the *make next segment non-tinable* control code is **XN** and it is defined by the *Next segment* field on the *Non-Tinable* tab of the *Survey.4d Create/Edit* panel.

The *make next segment non-tinable* control code makes the next segment point non-tinable. That is, the segment that the current point is the start of is non-tinable and hence not used as a breakline

in tins (triangulations).

Control Codes on the Templating tab

Record

The control code to denote that this is the first point of a new field template definition. The field template definition continues until the next *stop recording a field template* control code or a *start using a field template* control code.

If the field template is to have a name, then the *start recording* control code is followed by the *offset code* delimiter and then the name for the field template. If no name is given, then the field template defines the default field template.

For example, if *XA* starts recording for the default template, *XA.road* starts recording the field template called road

The default for the *start recording a field template* control code is **XA** and it is defined by the *Record* field on the *Templating* tab of the *Survey.4d Create/Edit* panel.

See the Section “Field Templates” for more information on field templates.

Start

The control code to denote that a field template is being used. This point takes the feature code and string number from the field template. If it is a named field template, then the control code is followed by the *offset code* delimiter and then the name of the field template.

The field template can also be used as a forward template, a reverse template or as a zig-zag template starting on either a zig or on a zag.

To denote using the field template as a forward template, add the *offset code* delimiter and *for*.

To denote using the field template as a reverse template, add the *offset code* delimiter and *rev*.

To denote zig-zag mode starting on a zig, add the *offset code* delimiter and *zig*.

To denote zig-zag mode starting on a zag, add the *offset code* delimiter and *zag*.

If anything other than ‘for’, ‘rev’ or ‘zag’ is given, the field template is used as a zig-zag template starting on a zig.

For example, if *XB* starts using the default template, *XB.road.zag* starts using the field template called road as a zig-zag field template starting on a zag.

The default for the *start using a template* control code is **XB** and it is defined by the *Start* field on

the *Templating* tab of the *Survey.4d Create/Edit* panel.

See the Section “Field Templates” for more information on field templates.

End

The control code to end the use of the current field template after the current point. That is, the current point uses the field template but subsequent measurements don't.

The default for the *stop using a template* control code is **XC** and it is defined by the *End* field on the *Templating* tab of the *Survey.4d Create/Edit* panel.

See the Section “Field Templates” for more information on field templates.

Pause

The control code to pause using the current field template. The current point does not use the field template.

The default for the *pause using a template* control code is **XD** and it is defined by the *Pause* field on the *Templating* tab of the *Survey.4d Create/Edit* panel.

See the Section “Field Templates” for more information on field templates.

Pause after

The control code to pause using the current field template and the current point does use the field template.

There is no default for the *pause after* control code and it is defined by the *Pause after* field on the *Templating* tab of the *Survey.4d Create/Edit* panel.

See the Section “Field Templates” for more information on field templates.

Continue

The control code to continue the use of a paused field template. The current point uses the field template.

The default for the *continuing using a field template* control code is **XE** and it is defined by the *Continue* field on the *Templating* tab of the *Survey.4d Create/Edit* panel.

See the Section “Field Templates” for more information on field templates.

Skip

The control code to skip point one or more points of the field template. The current point uses the next point *after* the skipped points from field template.

If more than one point is to be skipped then the control code is followed by the *offset code* delimiter and then number of points to be skipped.

For example, if *XF* is the skip points control code, *XF.2* skips two points. Note that just *XF* skips one point and the '.1' is not required.

The default for the *skipping field template points* control code is **XF** and it is defined by the *Skip* field on the *Templating* tab of the *Survey.4d Create/Edit* panel.

See the Section “Field Templates” for more information on field templates.

Insert

A default control code to insert a point in the field template can be added to this field. The point is inserted after the last point.

See the Section “Field Templates” for more information on field templates.

Delete

A default control code to delete a point in the field template can be added to this field. a number of points can be nominated for deletion.

See the Section “Field Templates” for more information on field templates.

Feature coding for traverse extraction (Non- Leica instruments)

In the example shown above, three distinct traverses were observed. The main traverse between stations 900 and 901 were given a feature code of TL and a string number of 1 (TL1). A typical observation description follows:

Setup on station 900. A foresight measurement was taken from 900 to 1001. A typical feature code may be:

TL1 FS1001. Where the block delimiter is a space(" ") breaking the feature code up into TL1 and FS1001. This tells the reduction that the observation was a traverse because it has a feature code of TL as specified in the traverse tab of the reduction panel. The foresight control code may be FS, telling the reduction that the observation is a foresight observation to a named point

Setup on station 1001. A backsight to station 900 was observed. A typical feature code may be:

TL1 BS900. Where BS is the backsight control code

A foresight to 1002 may be coded as:

TL1 FS1002.

And so forth.

The observation to station 1013 may be made at the same time as when observing to station 1007 from the setup station 1006. Simply changing the string number to 2 for the observation to 1013

will ensure that it is treated as a different traverse. i.e. TL2 FS1013.

The second traverse between stations 1006 and 902 were given a feature code of TL and a string number of 2 whilst the traverse between stations 1010 and 903 were given a feature code of TL and a string number of 3.

The feature code/ string number needs to be present for at least the foresight or measured leg of each of the traverse legs. If they are also present for the backsight, then foresight/backsight pairs will be grouped together and reciprocal calculations done for that leg.

Data Collector Definitions

Unfortunately, each brand of data collector has its own method of communicating with a computer and a software package.

To allow for a variety of data collectors, 12d Model lets the user create and edit data collector definitions which are simply user defined sets of data collector parameters stored under user specified names.

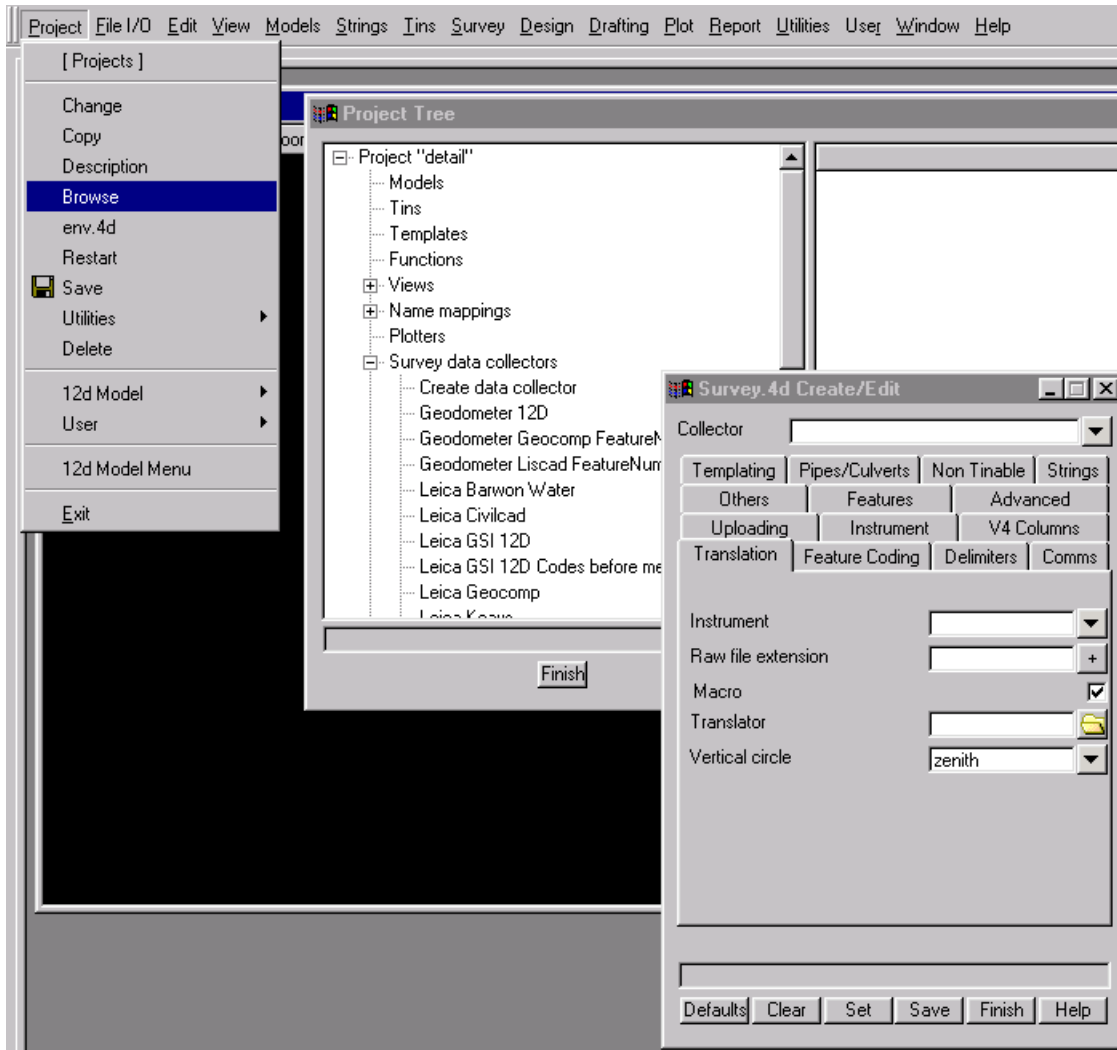

The set of data collector definitions are stored in a file but are created and edited using the 12d Model panel *Survey.4d Create/Edit*.

The *Survey.4d Create/Edit* panel is accessed via **Project => Browse**.

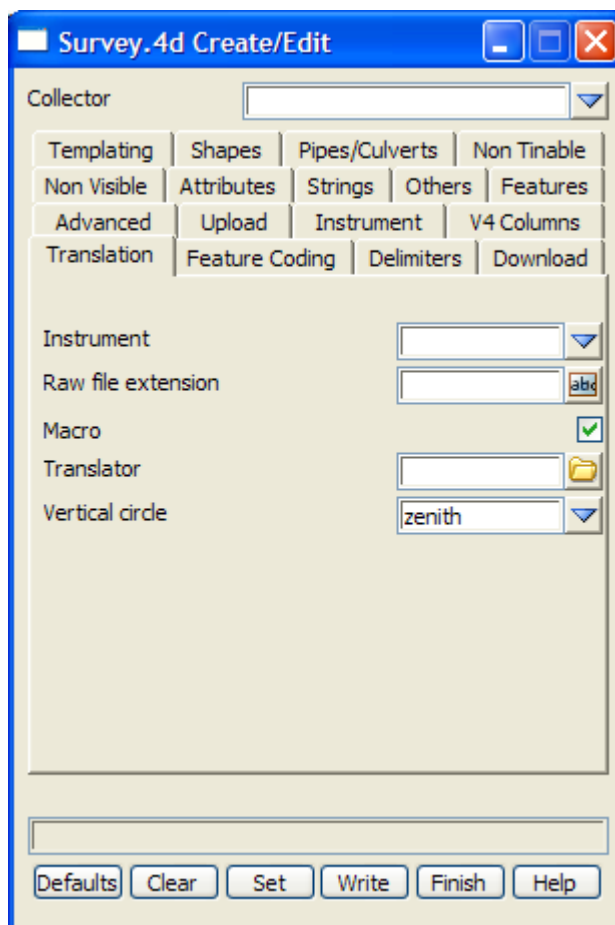

First select *Project => Browse* and then click on the + beside the Project name to expand the list of available information for the project. Then click on the + beside *Survey data collectors* to see the list of existing 12d data collector definitions.

Double click LB on *Create data collector* to create a new data collector definition, or double click LB on an existing data collector definition to examine and/or modify it.

The **Survey.4d Create/Edit** panel will then appear.

[survey_4d_create_edit](#)

The fields and buttons used in this panel have the following functions.

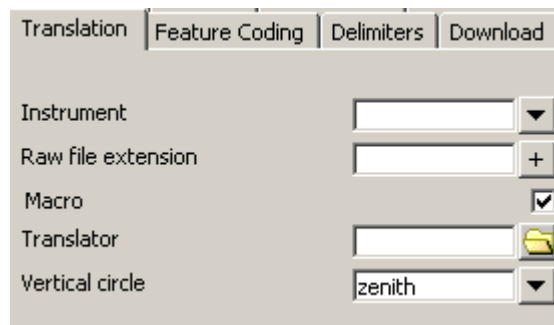

Field Description	Type	Defaults	Pop-Up
Collector <i>name of the data collector to create/edit.</i>	input		available data collectors
Defaults <i>set all the panel fields to default values.</i>	button		
Clear <i>clear the values in the panel fields in all the tabs.</i>	button		
Set <i>set the values in the panel fields for the given data collector for this session of 12d Model.</i> <i>WARNING - Set does not save the changes to the survey.4d file. To save the changes, click on the 'Save' button.</i>	button		
Save <i>store the data collector definitions to the survey.4d file.</i>	button		

For descriptions of each of the tabs on the panel, go to:

<i>Translation</i>	"Translation tab" .
<i>Feature coding</i>	"Feature Code tab" .
<i>Delimiters</i>	"Delimiters tab" .
<i>Download</i>	"Download tab" .
<i>Advanced</i>	"Advanced tab" .

<i>Upload</i>	“Upload tab” .
<i>Instrument</i>	“Instrument tab” .
<i>V4 Columns</i>	“V4 Columns tab” .
<i>Templating</i>	“Templating tab” .
<i>Shapes</i>	“Shapes tab” .
<i>Pipe/Culverts</i>	“Pipes/Culverts tab” .
<i>Non tinable</i>	“Non visible tab” .
<i>Non visible</i>	“Non visible tab” .
<i>Strings</i>	“Strings tab” .
<i>Others</i>	“Others tab” .
<i>Features</i>	“Features tab” .

Translation tab

Instrument input Geodimeter, Leica
 Nikon DR1, Nikon AP700, Sokkia 20/33
 Topcon GT700, Topcon FC5

type of data collector format.

Raw file extension input

file ending to use for the raw file when it is downloaded.

Macro tick box tick

*if tick, then the Translator pop-up list only shows 12d Model macros.
 If not ticked, then the Translator pop-up list only shows programs.*

Translator input list of translators in library
name of the macro/program to translate the raw survey file into the 12d field file format.

Vertical circle input zenith zenith, nadir
define the vertical circle zero.

Feature Code tab

String number position input before before feature code
 no string number
 after feature code

defines if the string number is before or after the feature code or is not used at all (no string number). When 'no string number' then the New string command is used to start new strings with the same feature code.

Tinability position	input	no tinability	before string no tinability after string
----------------------------	-------	---------------	--

defines the position or absence, of the tinability flag. This should only be used for compatibility with data coded for other systems such as CivilCAD. 12d has more flexible methods of defining tinability.

Numeric feature coding integer

if 'no string number' is given for String number position then Number feature coding is ignored.

If a number is given, then the feature code must be numeric and the given number is the length of the feature code (that is, the number of digits in the feature code).

If no number is given, then feature codes are alphabetical characters only except when a String code is used to separate the feature code and string number.

Delimiters tab

Translation	Feature Coding	Delimiters	Download
Command		*	
Comment		/	
Offset code		.	
String		+	
Backsight		BS	
Foresight			
Check measurement		CHK	
Extra coding		X	

Command	input	*
----------------	-------	---

defines the separator between the feature code/string number and op code commands. The delimiter characters can not be used in any other part of the command line.

Comment	input	/
----------------	-------	---

defines the separator for comments. Note that this can be a space.

Offset code	input	dot (.)
--------------------	-------	---------

defines the beginning of the offset code block. If the offset code block exists, it must come immediately after the Feature code/string number/tinability block. The offset code used R for radial, T for tangential, H for height.

String	input	+
---------------	-------	---

separates the feature code from the string number. Used when the feature code includes numbers. For example 110KVA+20 would be a feature code of 110KVA and a string number of 20.

Backsight	input	BS
------------------	-------	----

if the feature code is this control code then the measurement is to a backsight and not a point.

Foresight	input	
------------------	-------	--

if the feature code is this control code then the measurement is to a foresight and not a point.

Check measurement	input	CHK
--------------------------	-------	-----

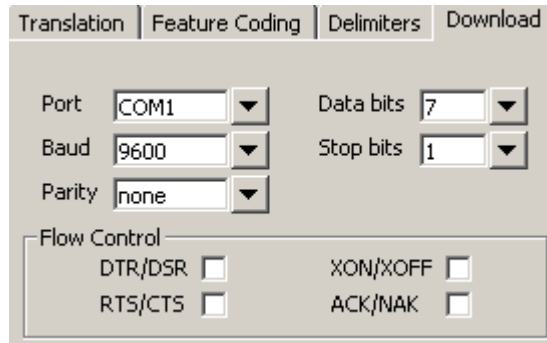

if the feature code is this control code then the measurement is a check measurement and not a point.

Extra coding	input	X
---------------------	-------	---

denotes that the information following is appended to the previous information for the measurement. This allows extra coding than may be allowed for on the measurement line. Mainly for Sokkia using the note (13NM) to add more information to the previous measurement line (07).

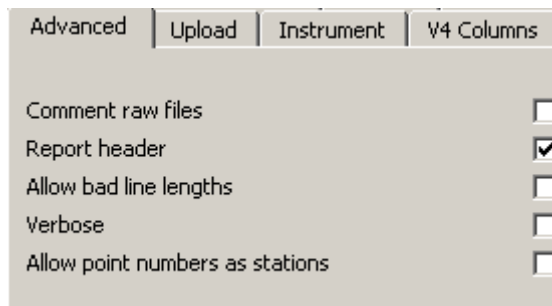

A feature code block must be on the measurement line or a measurement with no name will be created. Also a command block can't be split between two lines.

Download tab

Port	input	COM1	COM1 to COM4
	<i>port on the computer to use to communicate with the data collector for downloads.</i>		
Baud rate	input	9600	110, 300 ... 256000
	<i>baud rate to use for the computer port.</i>		
Data bits	input	7	5, 6, 7, 8
	<i>number of data bits to use.</i>		
Stop bits	input	1	0, 1, 1.5, 2
	<i>number of stop bits to use.</i>		
Parity	input	none	none, even, odd, mark, space
	<i>parity to use.</i>		
DTR/DSR, RTS/CTS, XON/XOFF, ACK/NAK	tick boxes		
	<i>flow control settings.</i>		

Advanced tab

Comment raw files	tick box
	<i>if tick, include the data from the raw survey file as comments in the 12d field file.</i>
Report header	tick box
	<i>if tick, include some header information as comments in the 12d field file.</i>
Allow bad line lengths	tick box

if tick, ignore the fact that the length of the line from the data collector is incorrect. This may lead to other errors so it should be used sparingly.

Verbose tick box

if tick, then extra information may be written to the Output window.

Allow point numbers as stations tick box

if tick, the point numbers for previous measurements can be used as stations for instrument setups, backsights, foresights and check measurements.

Note

When 12d Model starts up, it checks to see if an environment variable called DATA_COLLECTORS_4D exists and if it does, then the file it points to is used to provide the definitions for the data collectors.

If the environment variable is not set, then 12d Model searches for a file called **survey.4d** (this was **data_collectors_definitions** in V3.0) in the standard 12d Model search sequence for set up files.

Upload tab

Port	input	COM1	COM1 to COM4
			<i>port on the computer to use to communicate with the data collector for uploads.</i>
Baud rate	input	9600	110, 300 ... 256000
			<i>baud rate to use for the computer port.</i>
Data bits	input	7	5, 6, 7, 8
			<i>number of data bits to use.</i>
Stop bits	input	1	0, 1, 1.5, 2
			<i>number of stop bits to use.</i>
Parity	input	none	none, even, odd, mark, space
			<i>parity to use.</i>
DTR/DSR, RTS/CTS, XON/XOFF, ACK/NAK	tick boxes		
			<i>flow control settings.</i>
Extension	input		

ending of the file that will be uploaded. For example, typing in **sdr** means the file to upload ends in ".sdr"

CR/LF ? input cr, lf, crlf, lfcrlf, none
end of line characters - characters needed by the data recorder to denote the end of a line of data being uploaded to the data recorder.

Delay 1 input
the time between sending lines of data to the data recorder.

Process input
for some data recorders after a data line is sent, a text string needs to be sent to the data recorder to make it process the data line (e.g. GRE3 used a P).

Delay 2 input
the time between sending the process string and sending the next data line.

Ignore comms errors tick box
if tick, ignore any communication errors whilst uploading to the data recorder.

Instrument tab

Measurement/code order input after measurement code before measurement code after measurement

For Leica only where the feature code/string number record is separate to the measurement record. For all other data recorders the feature code block is in the same record as the measurement.

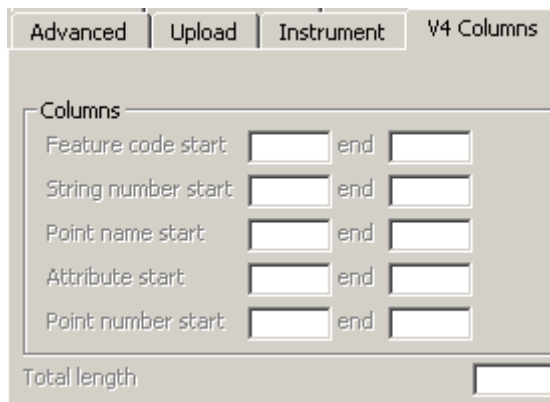

If 'code before measurement', then the feature code/ string number record for a measurement is entered before taking the measurement.

If 'code after measurement', then the feature code/ string number record for a measurement is entered after taking the measurement.

Sokkia 08KI as GPS points tick box

if tick, when converting reading an Sokkia SDR file, the "08KI" records are treated as points and no directly entered station co-ordinates.

V4 Columns tab

The V4 columns tab is for compatibility with 12d Model V4 field files which were of fixed column widths.

Feature code start/end input 1/6

the start and end column position for the feature code in the field file record.

String number start/end input 7/9

the start and end column position for the string number in the field file record.

Point name/Attribute/Point number start/endinput 22/30, 10/16, 17/20

the start and end column position for the point name/Attribute/Point number in the field file record.

Total length input

the total length of line expected.

Templating tab

Templating	Shapes	Pipes/Culverts	Non Tinable
Record			XA
Start			XB
End			XC
Pause			XD
Pause after			XDD
Continue			XE
Skip			XF
Insert			XI
Delete			XQ

Record input XA text

characters to denote the start of recording a field template. For example XA starts recording for the default template, XA.road starts recording the field template called road.

Start input XB text

characters to denote the start of using a field template. For example XB starts using the blank field template, XB.road starts using the field template called 'road'. XB.road.zig starts using 'road' a zig-zag field template and begins as a zag.

End input XC text

characters to denote stop using the current field template.

Pause input XD text

characters to denote temporarily stop using the current field template to take other measurements. The current point does not use the field template.

Pause after input XD text

characters to denote temporarily stop using the current field template to take other measurements. The current point does use the field template.

Continue input XE text

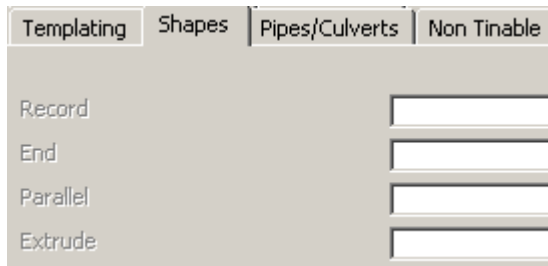

characters to denote continuing to use the current field template after a pause.

Skip input XF text
characters to denote that template points are to be skipped. For example XF means skip one field template point, XF.3 means skip three field template points.

Insert input XI text
characters to denote that template points are to be inserted. For example XI.FE01 means insert a template point of FE01 into the template after the last measured template point

Delete input XQ text
characters to denote that template points are to be deleted. For example XQ.3 means delete the next 3 pts from the template after the last measured template point

Shapes tab

Record input text
characters to denote the start of recording a shape. For example if RS was used, the code RS starts recording for the default shape, RS.shape_name defines the recording of a shape of name shape_name.

End input text
characters to denote stop using the current shape.

Parallel input text
*characters to denote the application of a shape by parallelling to the shape reference string. The code may be LK01*PS.shape_name
 Where the Parallel command is PS, the shape reference string is LK01 and the shape name = shape_name.*

Extrude input text
*characters to denote the application of a shape by extrusion to the shape reference string. The code may be LK01*ES.shape_name
 Where the Extrusion command is ES, the shape reference string is LK01 and the shape name = shape_name.*

Pipes/Culverts tab

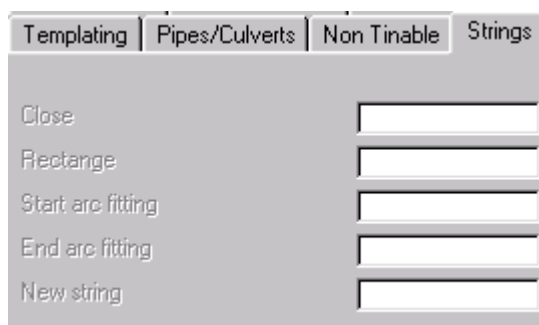

Invert input I text
characters to denote that the measurement was the an invert level.

Obvert input O text
characters to denote that the measurement was the an obvert level.

Centre input C text
characters to denote that the measurement was the a centreline level.

Note that these commands can also denote the diameter of a pipe or width and height of a culvert. For example, I.3 denotes the measurement was an invert level and it was a pipe of diameter 0.3 units. I.3x.4 denotes the measurement was an invert level and it was a box culvert of width 0.3 and height 0.4 units.

Strings tab

Close input C text
characters to denote that the string is closed. That is the current measurement is joined to the first point of the string.

Rectangle input R text
characters to denote that the string is a rectangle. That is the current measurement and the previous two points of the string are three points of a parallelogram and the fourth point is automatically created (and given a null height).

Start arc fitting input S text
characters to denote the start of arc fitting.

End arc fitting input E text
characters to denote the end of arc fitting.

New string input ST text
characters to denote the that the current measurement is the start of a new string, even if the string number has not changed.

Non visible tab

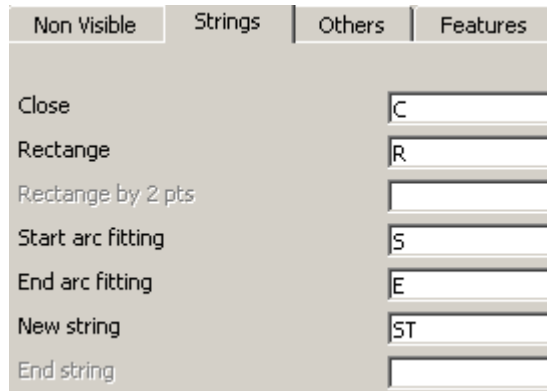

Point input text
characters to denote that the measurement is a non-visible point. That is, the point is not visible and is not included in a triangulation.

Previous segment input text
characters to denote that the measurement is the end of a non-visible segment. That is, the previous segment is not used as a breakline in a triangulation and it is not visible.

Next segment input text
characters to denote that the measurement is the start of a non-visible segment. That is, the next segment is not used as a breakline in a triangulation and is not visible.

Strings tab

Close input C text
characters to denote that the string is closed. That is the current measurement is joined to the first point of the string.

Rectangle input R text
characters to denote that the string is a rectangle. That is the current measurement and the previous two points of the string are three points of a parallelogram and the fourth point is automatically created (and given a null height).

Rectangle by 2 pts input text
characters to denote that the string is a rectangle. That is the previous two points of the string define one side and a offset defines the opposite side. Positive being to the right. The created points are given null height.

Start arc fitting input S text
characters to denote the start of arc fitting.

End arc fitting input E text
characters to denote the end of arc fitting.

New string input ST text
characters to denote the that the current measurement is the start of a new string, even if the string number has not changed.

End string input text
characters to denote the that the current measurement is at the end of a string, even if the string number has not changed on the next measurement.

Others tab

Under development

Features tab

Non Visible	Strings	Others	Features
	by radius		<input type="text"/>
	by diameter		<input type="text"/>

By radius input text

*characters to denote that the feature has a given radius. For example, if RA was used then TRE*RA2 would denote a feature code TRE with a radius of 2 units.*

There can be more than one set of characters that define 'By radius'. The sets are entered into the By radius field separated by a space. For example

RA RAD RD

would specify that RA and RAD and RD can be used to denote that the feature is defined by radius.

By diameter input text

*characters to denote that the feature has a given diameter. For example, if DI was used then TRE*DI2 would denote a feature code TRE with a diameter of 2 units.*

There can be more than one set of characters that define 'By diameter'. The sets are entered into the By diameter field separated by a space. For example

DI DIA DR

would specify that DI and DIA and DR can be used to denote that the feature is defined by diameter.

The 12d Field File Format

The detailed definition of the standardised 12d Field File will now be given. This is the file that all raw files are converted to before reduction in 12d Model.

A few definitions will be given, followed by the complete description of the 12d Field File.

The raw data files from different data collectors are all converted to the 12d field file format.

The 12d field file is ascii and has a name ending in **.fld**

Each line in the 12d field file is called a record and consists of an **operation code** (or *op code* for short) followed by zero or more tabs and pieces of information.

(a) zero fields

What actually follows the fixed header depends on the *op code*.

Hence the 12d field file record is:

op code
99

or

op code	tab	value	...	tab	value
02		abcS			fred

A number of conventions and definitions will be now given, followed by the complete description of the 12d Field File.

Important Note

Op codes are not the same as field codes. *Field codes* are entered by the surveyor in the field and may lead to one or more op codes being created in the 12d field file.

Please continue to the next section "Point Description" .

Point Description

The *feature codes* and *string numbers* are entered by the surveyor whilst surveying in the field and the *point numbers* are usually automatically created by the surveying instrument but may sometimes be entered into the instrument by the surveyor.

Other information can also be entered by the surveyor using **field codes** and associated information. How each field code and associated information is entered in the field *depends on the data recorder* and the *coding convention* being used. This is set up in the *Data Collector definitions* in 12d Model.

The data file from the instrument or data collector (raw file) is first converted in 12d Model to the 12d field file ready for loading into a 12d Model Survey Reduction function for reduction.

In most lines of the **12d field file**, a *feature code*, *string number*, *point number*, *point name* and *point text* are given and are stored next to each other separated by tabs.

The **feature code** and **string number** have already been described.

The **point number** is the EDM tacheometry measurement point number which is not normally entered by the user but is written in the raw data file by the data collector. This is stored as the point number for the vertex of the super string.

The **point name** is used to store the name of a station (see the next section on *named measurements*) and is supplied by the user with certain op codes. It is also used by some op codes that do not require an actual point name but have other special information that needs to be stored.

The **point text** is stored as vertex text for that vertex of the super string.

In the 12d field file, the *feature code*, *string number*, *point number*, *point name* and *point text* are given in this order and are separated by tabs. Each can be up to sixty-three characters in length. If the item is missing then a tab is still needed so there may be two or more sequential tabs.

For simplicity in describing the **12d field file**, the feature code, string number, point number, point name and point text are grouped together and called the **point description**.

Hence the **point description** consists of the following pieces of information separated by tabs:

- ▲ feature code (string name)
- ▲ string number
- ▲ point number
- ▲ point name
- ▲ point text

So it is convenient to think of the *point description* record as five columns of information:

feature code	string number	point number	point name	text
abc	01	1002	STN 4	freddie

Please continue to the next section “Measurements and Named Measurements” .

Measurements and Named Measurements

The **12d** field file allows five types of measurements that create points (vertices) in super strings. They are

- (a) directly entered co-ordinates measurement
- (b) EDM measurement (HA,VA,SD, + point_description.)
- (c) EDM measurement VD (HA,HD,VD + point_description.)
- (d) EDM measurement HT (HA,HD,HT, + point_description.)
- (e) three hair stadia measurement

Each type of measurement creates a new point which is appended to the previous points with the same *feature code* and *string number*.

The last such measurement is referred to as the *current measurement point* or *current point* and the string it is appended to is the *current string*.

If a *point_name* exists in the *point_description* for any of the three types of measurements, then it is called a **named measurement** and a one point super string of name *point_name* is created and mapped using the mapping file. The vertex text for the one point super string is the station prefix followed by *point_name*. The *point_name* is added to an internal list of named points for searching for co-ordinates.

Please continue to the next section “Existing Station Co-ordinates” .

Existing Station Co-ordinates

When setting up a new instrument, measuring to a backsight, doing a check measurement or manually entering a bearing to use as the bearing datum difference, the *point_name* or point number from the *point_description* is used to specify a point. The (x,y,z) co-ordinates for *point_name* are found by searching in the following order:

The difference between *point names* and *point numbers* is that *point names* are usually given by the user and should be a unique identifier for a point whilst for that same physical point a number of measurements (and hence point numbers) may be assigned (usually by the data collector). This may be particularly true of control station measurements where measurements are made to a given point name but each measurement is given a different point number by the data collector.

In most instances, a measurement to a point has a point number (from the data collector) and 12d automatically gives it the same point name as it is rare to measure a non-control point more than once (the point name can be over ridden by the user).

The names allow the reduction routine to search for the details of that point (e.g. coordinates) to allow for the reduction of further measurements. The order in which this searching takes place is as follows:

First search the Control model (if it exists):

1. A search is made of the control model for a string whose name is the same as the specified *point name*. If a string is found, the first point of the string is used for the (x,y,z) co-ordinates.
2. A search is made of the control model for a vertex of a string whose point number is the same as the specified *point name*. If a vertex is found its (x,y,z) co-ordinates are used.
3. If only a *point number* was specified, a search is made of the control model for a vertex of a string whose point number is the same as the specified *point number*. If a vertex is found its (x,y,z) co-ordinates are used.

Next search the already entered directly entered co-ordinates (DEC) in the field file:

4. A search is made of previously entered directly entered co-ordinates in the field file for a directly entered co-ordinate whose *point name* is the same as the specified *point name*. If a DEC is found, its (x,y,z) co-ordinates are used.
5. A search is made of previously entered directly entered co-ordinates in the field file for a directly entered co-ordinate whose *point number* is the same as the specified *point name*. If a DEC is found, its (x,y,z) co-ordinates are used.
6. A search is made of previously entered directly entered co-ordinates in the field file for a directly entered co-ordinate whose *point number* is the same as the specified *point number*. If a DEC is found, its (x,y,z) co-ordinates are used.

Next search the previous measurements in the field file:

7. A search is made of previous measurements in the field file for a measurement whose *point name* is the same as the specified *point name*. If a measurement is found, its (x,y,z) co-ordinates are used.
8. A search is made of previous measurements in the field file for a measurement whose *point number* is the same as the specified *point name*. If a measurement is found, its (x,y,z) co-ordinates are used.
9. A search is made of previous measurements in the field file for a measurement whose *point number* is the same as the specified *point number*. If a measurement is found, its (x,y,z) co-ordinates are used.
10. or finally, the user is asked to type in the (x,y,z) co-ordinates in a **Survey Data Define Station** panel. If a model is specified in the Add to model field of the panel, then a new one point super string is created with the name *point_name*, and as the vertex text for the point, the Station label prefix field value followed by *point_name*.

For a summary of the 12d Field File Op Codes, go to the section "Summary of 12d Field File Op Codes"

For the full description of the 12d Field File Op Codes, go to the section “Full Description of 12d Field File Op Codes”

Full Description of 12d Field File Op Codes

For a summary of the 12d Field File Op Codes, go to the section “Summary of 12d Field File Op Codes”

The record for each *op code* allowed in the 12d field file will now be described in detail.

For each *op code* record, two lines and a paragraph of description are given:

- ▲ The first line consists of the *op code* and a short description of the purpose of the code.
- ▲ The second line gives the full syntax of the record for that *op code*.
- ▲ The paragraph gives a detailed description of the *op code* record.

Optional information is enclosed in the square brackets []

All **angles** in the 12d field file are given in **decimal** degrees.

Important Note

Op codes are not the same as field codes. *Field codes* are entered by the surveyor in the field and may lead to one or more op codes being created in the 12d field file.

Op Code	Description of Record
1	<p>Four 10 character information blocks <i>01 block1 block2 block3 block4</i></p> <p>This information is ignored.</p>
2	<p>Directly entered coordinate measurement <i>02 Point_description X Y Z</i></p> <p>A <i>measurement</i> point is created with the <i>feature code</i> and <i>string number</i> from the <i>point_description</i> and given (x, y,z) co-ordinates. No reduction is needed.</p> <p>The <i>point_number</i> and <i>text</i> from the <i>point_description</i> are recorded as the point number and text for that vertex of the super string.</p> <p>If a <i>point_name</i> exists in the <i>point_description</i>, then it is a named measurement and a 4d point string of name <i>point_name</i> is created and mapped using the mapping file. The 4d text is the station prefix followed by <i>point_name</i>. The <i>point_name</i> is added to the internal list of named points for searching for co-ordinates.</p>
3	<p>New instrument point <i>03 Point_description instrument_height</i></p> <p>Setting up an instrument at the point with name given in the <i>point_name</i> section of the <i>point_description</i>. The (x,y,z) co-ordinates for <i>point_name</i> are found by first searching the control model, then the list of previously named point in the reduction, point numbers of previous measurements and finally if <i>point_name</i> is still not found, the user is asked to type in the (x,y,z) co-ordinates. A record is written to the report file.</p>
4	<p>Measurement to backsight <i>04 Point_description horizontal_circle vertical_circle slope_distance azimuth</i></p> <p>Measurement to a backsight whose name is given in the <i>point_name</i> section of the <i>point_description</i>. If the <i>Display panel for backsights</i> field in the Survey Data Reduce panel is tick, then the Survey Data Bearing Datum Difference panel shows the <i>bearing datum difference</i> and the <i>horizontal distance</i></p>

difference. A record is written to the report file. The units for *horizontal_circle* and *vertical_circle* are decimal degrees. The azimuth may be specified where no coordinate for the backsight point exists in decimal degrees.

5 New target height

05 *Target_height*

Set a new target height.

6 Check measurement

06 *Point_description horizontal_circle vertical_circle slope_distance*

A check measurement is made to the station given in the *point_name* section of the *point_description*. A two point super string (with name *point_name*) from the instrument point to the measured point is created in the default model for the check measurement. The instrument point name, the station name and the differences between the measurement point co-ordinates and the station co-ordinates are written as text along the super string. The differences between the measurement and the known point is also written to the report file. The units for *horizontal_circle* and *vertical_circle* are decimal degrees.

7 Measurement - HA, VA, SD

07 *Point_description horizontal_circle vertical_circle slope_distance*

Measurement made by the instrument. A *measurement* point is created with the *feature code* and *string number* from the *point_description*. The units for *horizontal_circle* and *vertical_circle* are decimal degrees.

The *point_number* and *text* from the *point_description* are recorded as the point number and text for that vertex of the super string.

If a *point_name* exists in the *point_description*, then it is a **named measurement** and a 4d point string of name *point_name* is created and mapped using the mapping file. The 4d text is the station prefix followed by *point_name*. The *point_name* is added to the internal list of named points for searching for co-ordinates.

9 Scale factor for subsequent distances

09 *Scale_factor*

Scale factor to apply to subsequent slope distances.

10 Three hair stadia measurement

10 *Point_description horizontal_circle vertical_circle bottom middle top*

Manual measurement. A *measurement* point is created with the *feature code* and *string number* from the *point_description*. The units for *horizontal_circle* and *vertical_circle* are decimal degrees.

The *point_number* and *text* from the *point_description* are recorded as the point number and text for that vertex of the super string.

If a *point_name* exists in the *point_description*, then it is a **named measurement** and a 4d point string of name *point_name* is created and mapped using the mapping file. The 4d text is the station prefix followed by *point_name*. The *point_name* is added to the internal list of named points for searching for co-ordinates.

11 Measurement - HA, HD, Height

11 *Point_description horizontal_circle horizontal_distance height*

Measurement made by the instrument. A *measurement* point is created with the *feature code* and *string number* from the *point_description*. The unit for *horizontal_circle* is decimal degrees.

The *point_number* and *text* from the *point_description* are recorded as the point number and text for that vertex of the super string.

If a *point_name* exists in the *point_description*, then it is a **named measurement** and a 4d point string of name *point_name* is created and mapped using the mapping file. The 4d text is the station prefix

followed by *point_name*. The *point_name* is added to the internal list of named points for searching for co-ordinates.

12 Measurement - HA, HD, Height difference

11 *Point_description horizontal_circle horizontal_distance height_difference*

Measurement made by the instrument. A *measurement* point is created with the *feature code* and *string number* from the *point_description*. The unit for *horizontal_circle* is decimal degrees.

The *point_number* and *text* from the *point_description* are recorded as the point number and text for that vertex of the super string.

If a *point_name* exists in the *point_description*, then it is a **named measurement** and a 4d point string of name *point_name* is created and mapped using the mapping file. The 4d text is the station prefix followed by *point_name*. The *point_name* is added to the internal list of named points for searching for co-ordinates.

15 Vertical circle correction

09 *Vertical_circle_in_decimal_degrees*

The *vertical_circle_in_decimal_degrees* is **subtracted** from the vertical circle value in any measurements. The units for *vertical_circle_in_decimal_degrees* is decimal degrees.

16 Multiply coded point

16 *Point_description*

Additional coding for the current measurement point created by op codes 02, 07 or 10. A new measurement point is created at the same position as the current measurement point but with the *feature code* and *string number* from the *point_description* for this op code.

The *point_number* and *text* from the *point_description* are recorded as the point number and text for that vertex of the super string.

If a *point_name* exists in the *point_description*, then it is a **named measurement** and a 4d point string of name *point_name* is created and mapped using the mapping file. The 4d text is the station prefix followed by *point_name*. The *point_name* is added to the internal list of named points for searching for co-ordinates.

17 Arc through previous three points

17 [*Point_description*]

If no *point_description* is given, then the current measurement point and the two previous points with the same *feature code* and *string number* as the current measurement point, are joined by an arc. If there is less than three such points, no arc is fitted.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* from the *point_description* exist, the last three previous measurement points of the same *feature code* and *string number* are joined by an arc. If the current measurement point has that *feature code* and *string number*, then it is the third of the three points used. If there is less than three points, no arc is fitted.

If *Point_number* exists, then the *feature code* and *string number* are taken from the previous measurement point **with** that point number. That point and the two measurement points previous to the predefined point of the same *feature code* and *string number*, are joined by an arc. If there is less than three points, no arc is fitted

18 Circle Feature

18 *Radius*

Creates a feature string with the given radius and centred on the current measurement point.

20 Close string*20 [Point_description]*

If no *point_description* is given, the current string is closed.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* from the *point_description* exist, the last previous string with that *feature code* and *string number* is closed.

If the *point number* from the *point_description* exists, then the string containing that point number will be closed.

21 Join last points of strings*21 Feature_code string_number_1 string_number_2*

In the final reduction, the last point of the string with the given *feature_code* and *string_number_1* is joined to the last point of the string with given *feature_code* and *string_number_2*. The created string has the given *feature_code* (no string number is needed since it is the final phase of reduction when the string numbers are dropped).

22 Join first to last point of strings*22 Feature_code string_number_1 string_number_2*

In the final reduction, the first point of the string with the given *feature_code* and *string_number_1* is joined to the last point of the string with given *feature_code* and *string_number_2*. The created string has the given *feature_code* (no string number is needed since it is the final phase of reduction when the string numbers are dropped).

23 Join first points of strings*23 Feature code string number_1 string number_2*

In the final reduction, the first point of the string with the given *feature code* and *string number 1* is joined to the first point of the string with given *feature code* and *string number 2*. The created string has the given *feature code* (no string number is needed since it is the final reduction when the string numbers are then dropped).

28 Add text to the string name*28 [Point_description] Text*

Text is appended to the string name. For example, if 1.200 is entered, "1.200" is appended to the string name.

If no *point_description* is given, *Text* is appended to the string name of the current string.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, then the last previous string with that *feature code* and *string number* has *Text* appended to the string name.

If the *point number* exists, then the string containing that point number has *Text* appended to the string name.

29 Note or memo*29 Comments*

Any text may be entered and will be added to the check measurements model at the position of the current measurement point.

30 Remove height from a point - that is make it a null height*30 [Point_description]*

If no *point_description* is given, the height of the current measurement point is set to null.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, then the height of the last point of the previous string with that *feature code* and *string number* is set to null.

If the *point number* exists, then the height of the point with that point number is set to null.

37 **Rectangle by two points**

37 [*Point_description*] *offset_in_metres*

The rectangle is defined by two points (reference side) and a offset.

If a positive offset value is given, two points will be created to the right of the reference side.

If a negative offset value is given, two points will be created to the left of the reference side.

If no *point_description* is given, the two new points will be joined to the given points in a closed rectangular string, and will have the same feature code as the points given.

If the *feature code* and *string number* exist, then a search is made for the last occurrence of two points with the same *feature code* and *string number*. If found, then these points are used to define the reference side of the rectangle.

If the *point number* exists, then a search is made for the last occurrence of two points with the same *feature code* and *string number* as the point given by the point number. If found, then these points are used to define the reference side of the rectangle.

Two consecutive rectangles are unable to be defined side by side. In other words if the two points given are part of string of greater than two vertices, the command will only work for sets of two points that are exclusively defined. i.e. For a 5 point string, a rectangle can be defined by points 1 and 2, and 4 and 5.

38 **Make the previous segment non-tinable**

38 [*Point_description*]

If no *point_description* is given, the previous segment containing the current measurement point is set to non-tinable. That is, it will not be treated as a breakline in triangulations.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, then the last segment of the previous string with that *feature code* and *string number* is set to non-tinable.

If the *point number* exists, then the segment containing the point with that point number as an end point, is set to non-tinable.

39 **Make the next segment non-tinable**

39 [*Point_description*]

If no *point_description* is given, the next segment containing the current measurement point as a starting point is set to non-tinable. That is, it will not be treated as a breakline in triangulations.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, then the segment that is created in the future from the last point of the previous string with that *feature code* and *string number* is set to non-tinable.

If the *point number* exists, then the segment containing the point with that point number as a start point, is set to non-tinable.

40 **Make a point non-tinable**

40 [*Point_description*]

If no *point_description* is given, the current measurement point is set to non-tinable. That is, it will not

be included in triangulations.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, then the last point of the previous string with that *feature code* and *string number* is set to non-tinable.

If the *point number* exists, then the point with that point number is set to non-tinable.

41 Add additional text for the current measurement point

41 Text

The given *text* is added to the end of any existing text for the current measurement point. Any spaces from column four onwards will be part of the text.

42 Add a radial offset

42 [*Point_description*] *Radial_offset_in_metres*

The *radial_offset_in_metres* is used to adjust the position of the specified point by a plan distance from the specified points original position, along the plan line joining the current station to the specified point. A positive offset is away from the station, negative is toward the station.

If no *point_description* is given, the offset is used to adjust the position of the current measured point.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, then the last point of the previous string with that *feature code* and *string number* is adjusted.

If the *point number* exists, then the point with that point number is adjusted.

43 Add a tangential offset

43 [*Point_description*] *Tangential_offset_in_metres*

The *tangential_offset_in_metres* is used to adjust the position of the specified point by a plan distance from the specified points original position, at rights angles to the plan line joining the current station to the specified point. A negative offset is to the left (looking from the station), and positive is to the right (looking from the station).

If no *point_description* is given, the offset is used to adjust the position of the current measured point.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, then the last point of the previous string with that *feature code* and *string number* is adjusted.

If the *point number* exists, then the point with that point number is adjusted.

44 Add a height offset

44 [*Point_description*] *Height_offset_in_metres*

If the height of the specified point is not null, then the *height_offset_in_metres* adjusts the height of the point. A positive offset adds to the height, a negative offset reduces the height.

If no *point_description* is given, the offset is used to adjust the position of the current measured point.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, then the last point of the previous string with that *feature code* and *string number* is adjusted.

If the *point number* exists, then the point with that point number is adjusted.

45 Make a parallelogram from the last three measurement points*45 [Point_description]*

If no *point_description* is given, the current measurement point and the two previous points from the current string are used and a fourth point is created to form a parallelogram (squashed rectangle) and the height of the fourth point is set to null. The string is then closed.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, the last three points with that *feature code* and *string number* are used and a fourth point is created to form a parallelogram (squashed rectangle) and the height of the fourth point is set to null. The string is then closed.

If the *point number* exists, then the *feature code* and *string number* of the point with that point number are used and processed as above. Note that the point with the point number is not necessarily used.

46 Make the string a breakline or not*46 [Point_description] [mode]*

The *point_description* is used to select a string and the *mode* is used specify if the string is a breakline or not.

point_description:

If no *point_description* is given, the current string is selected.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, the last string with that *feature code* and *string number* is selected.

If the *point number* exists, then the string containing the point with that point number is selected.

mode:

If no *mode* is given, the selected string is set as a point string (that is, not a breakline).

If *mode* is given, then

if *mode* is 0, the selected string is set to a point string and hence is not a breakline.

if *mode* is 1, the selected string is set to a *line* string and is therefore a breakline

47 Start a new string using the same feature code and string number*47 [Point_description]*

If no *point_description* is given, the current string is terminated (without including the current measurement point) and the current measurement point becomes the first point of a new string with the same feature code and string number.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, then the last point of the previous string with that feature code and string number becomes the first point of a new string with the same *feature code* and *string number*.

If the *point number* exists, then the previous string containing the point with that point number is terminated *before* the point number point, and the point becomes the first point of a new string with the *same feature code* and *string number*.

48 End a string -*48 [Point_description]*

If no *Point_description* exists, the current string is terminated (including the current measurement point).

If *Feature_code* and *String_number* exist, then the last point of the previous string with that feature code and string number becomes the last point of that string.

If *Point_number* exists, then the previous string containing the point with that point number is terminated *after* the point number point

50 Specify the bearing to correct for true north - used as the bearing datum difference

50 *Point_description bearing_in_decimal_degrees*

The *bearing_in_decimal_degrees* is used as the bearing datum difference for the current instrument set up. The *point_name* in the *point_description* and the *bearing_in_decimal_degrees* are written to the report file.

51 Start using an existing field template

51 *Template_name zig_zag_mode*

Start using the field template *Template_name*. If *Template_name* is blank, the default field template is used.

If *mode* is "for", then the field template is used as a *forward* template.

"rev", then the field template is used as a *reverse* template.

"zig", then the field template is used as a *zig_zag* template and is used in the *forward* definition direction first (that is starts on a zig).

"zag", then the template is used as a *zig_zag* template and is used in the *reverse* direction first (that is, starts on a zag).

If *mode* is blank, or anything other than "for", "rev", or "zag" then the field template is used as a *zig-zag* template starting on a *zig*.

52 Finish using a field template or finish recording a field template

52

Stops using the current field template or stops recording a field template.

53 Pause using the current field template

53

Pause using the current field template or defining a field template, until a continue field template (54) or a finish field template (52) code is given.

54 Continue the current field template

54

Continue using or defining the current field template, which has been stopped by a *Pause* field template command (53). The *Continue* command only needs to be given once and applies to all following measurements until another *Pause* or *Finish* command is given.

55 Start recording a field template

55 [*Template_name*]

Start recording a field template with the name *Template_name*. If *Template_name* is blank, then it is the default field template that is defined. The *feature_code* and *string_number* of the following measurements until a *Finish* code (52) are stored as the field template. There is no limit to the number of points in a field template.

56 Skipping picking up points when using a field template

56 [*num_skipped_points*]

Allows the user to skip picking up one or more points from the field template currently being used. The next measurement takes the *feature_code* and *string_number* from the next point of the field template definition. If *num_skipped_points* is missing, then only one point is skipped otherwise *num_skipped_points* are skipped.

57 Delete points on a field template - after the measurement of last point*57 [num_points_to_delete]*

Allows the user to delete one or more points from the field template currently being used. The *next measurement* takes the *feature_code* and *string_number* from the next point of the field template definition.

58 Insert points when using a field template - after the measurement of last point*58 Feature_code String_number Multiple_code_flag Insert_special_flag*

Allows the user to insert points into the field template currently being used. The *next measurement* takes the *feature_code* and *string_number* from the next point of the field template definition.

If the *Multiple_code_flag = 1*, then the *feature code* will be added to the previous defined template point else if *Multiple_code_flag = 0* (default), it will be added to the template as a separate point.

If the insert is done at the end of a section and the *Insert_special_flag = 1* the point will be added to the end of the current template section else it will be at the start of the next section.

60 Arc through next three points*60 [Point_description]*

If no *point_description* is given, an arc is inserted through the current measurement point and the next two measured points with the same feature code and string number as the current measurement point. If there is less than three points, no arc is fitted.

If a *point_description* exists, then either the *feature code* and/or *string number* and/or the *point number* section of the *point_description* can be used.

If the *feature code* or *string number* from the *point_description* exist, a search is made for a previously defined measurement with the same feature code or string number. An arc is inserted through this previous measurement and the next two measured points following this previous measurement with the same feature code and string number, as given in *point_description*. If the current point has that feature code and string number, then it is the first of the three points. If there is less than three points, no arc fitted.

If the *point number* exists, then the *feature code* and *string number* are taken from the previous measurement point **with** that point number, and an arc is inserted through that point and the next two measurement points with the same *feature code* and *string number*. If there is less than three points, no arc is fitted

61 Start of arc through sets of three points until end of string, or a 62 occurs*61 [Point_description]*

If no *point_description* is given, arcs are inserted through the following sets of measurement points with the same feature code and string number as the current measurement point. The current measurement point is the first of the points.

The arcs are fitted as follows - the first arc is fitted through points one, two and three, the next arc through points three, four and five etc. If the current point has that feature code and string number, then it is the first of the points. If there is less than three points, then no arc is fitted.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, a search is made for a previously defined measurement with the same feature code or string number. An arc is inserted through the following measured points with the same feature code and string number as given in *point_description*. If the current point has that feature code and string number, then it is the first of the points.

If the *point number* exists, then the *feature code* and *string number* are taken from the previous measurement point **with** that point number, and arcs are inserted through that point and the following measured points with the same *feature code* and *string number*.

62 End the arcs begun by a 61 command*62 [Point_description]*

If no *point_description* is given, then the fitting of arcs through the points of the current string is stopped. The current measurement point is the last of the points used in the arc fitting.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* from the *point_description* exist, then the fitting of arcs through the points of the previous string with the same *feature code* and *string number* is stopped. If the current measurement point has that feature code and string number, then it is the last point used in the arc fitting.

If the *point number* from the *point_description* exists, then the point with that point number is the last point used in the arc fitting.

If 12d Model encounters an *End Arcs* (62) but no *Start Arcs through sets of three points* (61) command for the string, then a *Start Arcs through sets of three points* (61) is assumed to apply at the beginning of the string and hence arc fitting will be applied to the entire string.

There are op codes for adding user defined attributes to:

- (a) the current string being measured (i.e. the string containing the current measurement point)
 - (b) the current measurement point
 - (c) the next segment from the current measurement point (i.e. the segment joining the current measurement point and the *next* measured point *of the same feature code and string number*)
- or
- (d) the previous segment to the current measurement point (i.e. the segment joining the current measurement point to the previous measured point *of the same feature code and string number*).

If there is no name for the attribute (name is just spaces or a tab), then the attribute is *unnamed*. The attributes are coded in the following way:

68 Add an integer user defined attribute to the current string*68 Name Integer*

Add an user defined integer attribute to the current string.

69 Add a real user defined attribute to the current string*69 Name Real*

Add a real (floating point) user defined attribute to the current string.

70 Add text user defined attribute to the current string*70 Name Text*

Add a text user defined attribute to the current string.

71 Add integer user defined attribute to the current point*71 Name Integer*

Add an integer user defined attribute to the current measurement point.

72 Add real user defined attribute to the current point*72 Name Real*

Add a real (floating point) user defined attribute to the current measurement point.

73 Add text user defined attribute to the current point*73 Name Text*

Add a text user defined attribute to the current measurement point.

74 Add integer user defined attribute to the next segment*74 Name Integer*

Add an integer user defined attribute to the next segment from the current measurement point.

75 Add real user defined attribute to the next segment*75 Name Real*

Add a real (floating point) user defined attribute to the next segment from the current measurement point.

76 Add text user defined attribute to the next segment*76 Name Text*

Add a text user defined attribute to the next segment from the current measurement point.

77 Add integer user defined attribute to the previous segment*77 Name Integer*

Add an integer user defined attribute to the previous segment for the current measurement point.

78 Add real user defined attribute for the previous segment*78 Name Real*

Add a real (floating point) user defined attribute to the previous segment for the current measurement point.

79 Add text user defined attribute to the previous segment*79 Name Text*

Add a text user defined attribute to the previous segment for the current measurement point.

In addition, extra codes allow special 12d Model pipe strings to be coded in the field

80 Pipe invert point (bottom of the pipe)*80 [Point_description]*

If no *point_description* is given, the current measurement point is on the invert (bottom) of a pipe. This is the default for measurements to points on pipe strings. If the point is not part of a pipe string, it is ignored.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, the last point of the previous string with the same *feature code* and *string number* as given in *point_description* is on the invert (bottom) of a pipe. If the point is not part of a pipe string, it is ignored.

If the *point number* exists, then the point with that point number is on the invert (bottom) of a pipe. If the point is not part of a pipe string, it is ignored.

81 Pipe axial point (centre of the pipe)*81 [Point_description]*

If no *point_description* is given, the current measurement point is on the axis (centre) of a pipe. If the point is not part of a pipe string, it is ignored.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, the last point of the previous string with the same *feature code* and *string number* as given in *point_description* is on the axis (centre) of a pipe. If the point is not part of a pipe string, it is ignored.

If the *point number* exists, then the point with that point number is on the axis (centre) of a pipe. If the point is not part of a pipe string, it is ignored.

82 Pipe obvert point (top of the pipe)

82 [*Point_description*]

If no *point_description* is given, the current measurement point is on the obvert (top) of a pipe. If the point is not part of a pipe string, it is ignored.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, the last point of the previous string with the same *feature code* and *string number* as given in *point_description* is on the obvert (top) of a pipe. If the point is not part of a pipe string, it is ignored.

If the *point number* exists, then the point with that point number is on the obvert (top) of a pipe. If the point is not part of a pipe string, it is ignored.

83 Start recording a shape - before the measurement

83 [*Shape_name*]

Start recording a shape with the name *Shape_name*. If *Shape_name* is non-blank, then the default field Shape is defined by the *feature_code* and *string_number* of the following measurements until a *Finish* code (84) are stored as the shape. There is no limit to the number of points in a shape.

See the Section “Field Templates” for more information on field templates.

84 Finish using a shape definition or finish recording a shape - after the measurement

Stops using the current shape or stops recording a shape.

85 Shape parallel

85 [*Shape_name*] [*Point_description*]

Takes all the points on the defined shape of *Shape_name* and parallels them the entire length of the string. Once paralleled, a number of strings are created.

If *Feature_code* and *String_number* exist, the last string with the same *feature code* and *string number* has the shape applied to the entire length of the string.

If *Point_number* exists, then the string containing that point number has the shape applied to the entire length of the string.

86 Shape extrude

86 [*Shape_name*] [*Point_description*]

Takes the defined shape of *Shape_name* and extrudes it along the entire length of the string. Once extruded, only one strings is created which contains all the shape information.

If *Feature_code* and *String_number* exist, the last string with the same *feature code* and *string number* has the shape applied to the entire length of the string.

If *Point_number* exists, then the string containing that point number has the shape applied to the entire length of the string.

92 Remove all z-values for a string (i.e. make all z-values null)

92 [*Point_description*]

If no *point_description* is given, all z-values for the current string are removed.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, the last string with the same *feature code* and *string number* has all its z-values removed.

A *point-line type* can be embedding as a 0 or 1 in the *point name* part of the *point description* field. A zero value specifies a point string, and a non-zero value specifies a line string. If the field was omitted, a line string is assumed.

The point-line type may be overridden by the mapping file.

93 Set the Point-line type

93 [*Point_description*]

A *point-line type* can be embedding as a 0 or 1 in the *point name* part of the *point description* field. A zero value specifies a point string, and a non-zero value specifies a line string. If the field was omitted, a line string is assumed.

If no *point_description* is given, the point-line type for the current string is set to *line*.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, the point-line type is set for the last previous string with the same *feature code* and *string number*.

If the *point number* exists, then the point-line type is set for the string containing that point number.

The point-line type may be overridden by the mapping file.

94 Use name library file/ mapping file for vertex text on the string - name mapping

94 [*Point_description*]

If this op code exists then during reduction, vertex text is creating using either the name library, or if the name library doesn't exist, the map file. If neither exist then the op code is ignored.

if a name library is used and the feature code of the string is found in the first column of the name library, then the entry from the second column of that row will be used as text for *all* vertices of the string that don't already have vertex text. As a default, the string is set as a point string.

if the map file is used and the feature code of the string is found in the first column of the map file, then the *string name* field of the map file is used as vertex text for all vertices that don't already have text. As a default, the string is set as a point string.

If no *point_description* is given, then name mapping is applied to the current string.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, then name mapping is applied to the last previous string with the same *feature code* and *string number*.

If the *point number* from the *point_description* exists, then name mapping is applied to the string containing that point number.

A *point-line type* can be embedding as a 0 or 1 in the *point name* part of the *point description* field. A zero value specifies a point string, and a non-zero value specifies a line string. If the field was omitted, a line string is assumed.

The point-line type may be overridden by the mapping file.

95 Pipe string

95 [*Point_description*] *diameter*

Pipe strings are always line strings and are stored with the justification of the majority of the string points. Individual pipe points are picked up either top (obvert), centre (axial) or bottom (invert) of the pipe using op codes 80, 81 and 82.

If no *point_description* is given, the current string is created as a pipe string with the given diameter.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, the last string with the same *feature code* and *string number* is created as a pipe with the given diameter.

If the *point number* exists, then the string containing that point number is created as a pipe string with the given diameter.

96 Culvert string

96 [*Point_description*] *width height*

Culvert strings are always line strings and are stored with the justification of the majority of the string points. Individual culvert points are picked up either top (obvert), centre (axial) or bottom (invert) of the culvert using op codes 80, 81 and 82.

If no *point_description* is given, the current string is created as a culvert string with the given width and height.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, the last string with the same *feature code* and *string number* is created as a culvert with the given width and height.

If the *point number* exists, then the string containing that point number is created as a culvert string with the given width and height.

99 Terminate processing

99

Stop processing the 12d field file at this line. Useful for debugging errors.

107 Make the previous segment invisible - after the measurement

107 [*Point_description*]

If no *Point_description* exists, the previous segment containing the current measurement point is set to invisible.

If the *Feature_code* and *String_number* exist, then the last segment of the previous string with that *feature code* and *string number* is set to invisible.

If *Point_number* exists, then the segment containing the point with that point number as an end point, is set to invisible.

108 Make the next segment invisible - after the measurement for the first point of the segment

108 [*Point_description*]

If no *Point_description* exists, the next segment containing the current measurement point as a starting point is set to invisible.

If the *Feature_code* and *String_number* exist, then the segment that is created in the future from the last point of the previous string with that *feature code* and *string number* is set to invisible.

If *Point_number* exists, then the segment containing the point with that point number as a start point, is set to invisible.

109 Make a point invisible - after the measurement

109 [*Point_description*]

If no *Point_description* exists, the current measurement point is set to invisible.

If *Feature_code* and *String_number* exist, then the last point of the previous string with that *feature code* and *string number* is set to invisible.

If *Point_number* exists, then the point with that point number is set to invisible.

110 Start buildings face observations - before the measurements

110 [Building_name]

Start recording a field template with the name *Building_name*. If *Building_name* is non-blank, then the default building face is defined. The *feature_code* and *string_number* of the following measurements until a *Finish* code (111) are stored as the building face. There is no limit to the number of points in a building face.

111 End building face observations

111 [Building_name]

If no *Building_name* exists, the current building face observation set is finished (including the current measurement point).

Notes

1. Arc fitting is applied *after* the Joins are processed. Hence the new joined strings are created and then curve fitting is applied according to the arc codes (start arc, end arc, fit arcs, stop fitting arcs etc.) on any vertex of the string.
2. The *point description* has several pieces of information embedded in it and has been described in the previous section. For some op codes, the *point name* section of the *point description* is used to hold other information.

For a summary of the 12d Field File Op Codes, go to the section “Summary of 12d Field File Op Codes”

Summary of 12d Field File Op Codes

Op Code	Description of Record
-2	Comment
-1	Error
01	Header Information
02	Directly entered coordinate measurement
03	New instrument setup point
04	Measurement to backsight
05	New target height
06	Check measurement
07	Measurement - HA, VA, SD
09	Scale factor for subsequent distances
10	Three hair stadia measurement
11	Measurement - HA, HD, Ht
12	Measurement - HA, HD, Ht diff
15	Vertical circle correction
16	Multiply coded point
17	Arc through previous three points
18	Circle Feature
20	Close string
21	Join last points of strings
22	Join first to last point of strings
23	Join first points of strings
28	Add text to the string name
29	Note or memo
30	Remove height from a point - that is make it a null height
37	Rectangle by two points
38	Make the previous segment non-tinable
39	Make the next segment non-tinable
40	Make a point non-tinable
41	Add additional text for the current measurement point
42	Add a radial offset
43	Add a tangential offset
44	Add a height offset
45	Make a parallelogram from the last three measurement points
46	Make the string a breakline or not
47	Start a new string using the same feature code and string number
48	String end
50	Specify the bearing to correct for true north - used as the bearing datum difference
51	Start using an existing field template
52	Finish a field template or finish recording a field template
53	Pause the current field template until a continue op code (54) or a finish template (52)
54	Continue the current field template
55	Start recording a field template
56	Skip picking up one or more points from a field template
57	Delete one or more points from a field template
58	Insert a point into a field template
60	Arc through next three points
61	Start of arc through sets of three points until end of string, or a 62 occurs
62	End the arcs begun by a 61 command
68	Add an integer user defined attribute to the current string
69	Add a real user defined attribute to the current string
70	Add text user defined attribute to the current string
71	Add integer user defined attribute to the current point
72	Add real user defined attribute to the current point
73	Add text user defined attribute to the current point
74	Add integer user defined attribute to the next segment

- 75 Add real user defined attribute to the next segment
- 76 Add text user defined attribute to the next segment
- 77 Add integer user defined attribute to the previous segment
- 78 Add real user defined attribute for the previous segment
- 79 Add text user defined attribute to the previous segment
- 80 Pipe or culvert invert point (bottom of the pipe or culvert)
- 81 Pipe or culvert axial point (centre of the pipe or culvert)
- 82 Pipe or culvert obvert point (top of the pipe or culvert)
- 83 Start recording/measuring a shape
- 84 End measuring a shape
- 85 Parallel an existing shape
- 86 Extrude an existing shape
- 92 Remove all z-values for a string (i.e. make all z-values null)
- 93 Set the Point-line type
- 94 Use name library file/ mapping file for vertex text on the string - name mapping
- 95 Pipe string
- 96 Culvert string
- 99 Terminate processing
- 107 Last segment of point invisible
- 108 Next segment of point invisible
- 109 Point invisible
- 110 Building face start recording
- 111 Building face end recording

Batch Typed Entry

Typed entry can be used to enter survey data into a 12d Field File and reduced using the Survey data Editor.

12d Model uses the following 12d field file ops code:

Op Code	Description of Record
-2	Comment
-1	Error
01	Header Information
02	Directly entered coordinate measurement
03	New instrument setup point
04	Measurement to backsight
05	New target height
06	Check measurement
07	Measurement - HA, VA, SD
09	Scale factor for subsequent distances
10	Three hair stadia measurement
11	Measurement - HA, HD, Ht
12	Measurement - HA, HD, Ht diff
15	Vertical circle correction
16	Multiply coded point
17	Arc through previous three points
18	Circle Feature

21	Join last points of strings
22	Join first to last point of strings
23	Join first points of strings
28	Add text to the string name
29	Note or memo
30	Remove height from a point - that is make it a null height
37	Rectangle by two points
38	Make the previous segment non-tinable
39	Make the next segment non-tinable
40	Make a point non-tinable
41	Add additional text for the current measurement point
42	Add a radial offset
43	Add a tangential offset
44	Add a height offset
45	Make a parallelogram from the last three measurement points
46	Make the string a breakline or not
47	Start a new string using the same feature code and string number
48	String end
50	Specify the bearing to correct for true north - used as the bearing datum difference
51	Start using an existing field template
52	Finish a field template or finish recording a field template
53	Pause the current field template until a continue op code (54) or a finish template (52)
54	Continue the current field template
55	Start recording a field template
56	Skip picking up one or more points from a field template
57	Delete points from a field template
58	Insert points in a field template
60	Arc through next three points
61	Start of arc through sets of three points until end of string, or a 62 occurs
62	End the arcs begun by a 61 command
68	Add an integer user defined attribute to the current string
69	Add a real user defined attribute to the current string

- 70 Add text user defined attribute to the current string
- 71 Add integer user defined attribute to the current point
- 72 Add real user defined attribute to the current point
- 73 Add text user defined attribute to the current point
- 74 Add integer user defined attribute to the next segment
- 75 Add real user defined attribute to the next segment
- 76 Add text user defined attribute to the next segment
- 77 Add integer user defined attribute to the previous segment
- 78 Add real user defined attribute for the previous segment
- 79 Add text user defined attribute to the previous segment
- 80 Pipe or culvert invert point (bottom of the pipe or culvert)
- 81 Pipe or culvert axial point (centre of the pipe or culvert)
- 82 Pipe or culvert obvert point (top of the pipe or culvert)
- 83 Start recording/measuring a shape
- 84 End measuring a shape
- 85 Parallel an existing shape
- 86 Extrude an existing shape
- 92 Remove all z-values for a string (i.e. make all z-values null)
- 93 Set the Point-line type
- 94 Use name library file/ mapping file for vertex text on the string - name mapping
- 95 Pipe string
- 96 Culvert string
- 99 Terminate processing
- 107 Last segment of point invisible
- 108 Next segment of point invisible
- 109 Point invisible
- 110 Building face start recording
- 111 Building face end recording

Users can enter text for each measurement (observation 09 record or position 08 record) which is appended to the end of the record and this is used as the text of blocks that are interpreted according to the descriptions given in the earlier section “Field Coding for Non Leica Instruments” .

The '13' record can also be used after a measurement record to add additional information to the preceding blocks using the *extra coding* control code at the end of the previous line (see “Extra Coding” in the section “Control Code Blocks”

Strictly speaking the Sokkia SDR20/33 formats use fixed length lines and if the lengths are incorrect, an error message will be written to the Output Window. For example,

'Line 248 line incorrect length. required length is 58. received length is 50.'

These messages often appear after a raw file has been manually edited because most editors remove space padding at the end of a line.

For the full description of the 12d Field File Op Codes, go to the section “Full Description of 12d Field File Op Codes”

B 12D and Sokkia Instruments (SDR Files)

This Section deals with interfacing 12d with Sokkia SDR20/33 data formats specifically with the SDR33 electronic field book (Controller). Other controllers and instruments such as the powerset range of total stations also use these formats.

A large number of instruments support the Sokkia SDR data format including (Trimble Total Station ACU), not just those from Sokkia.

For the topic:

1. Field Coding see the section “Coding For SDR Files”
2. Sending raw file from controller to 12d “Downloading SDR File To 12d”
3. Converting raw data to field file see the section “Converting SDR Raw File To Field File”
4. Creating Points upload file see the section “Creating SDR Point Upload File”
5. Creating Road upload file see the section “Creating SDR Roads Upload File”
6. Creating Tin upload file see the section “Create Tin upload file”

Coding For SDR Files

The Sokkia SDR20/33 data formats are used as raw data files by 12d Model and are converted into a 12d Field File before reduction. 12d Model uses the following Sokkia records:

01	Record header - SDR format
02	Station details
03	Target height
07	Back bearing details
08	Position - directly entered co-ordinates
09	Observation - measurement
13	Comment or continuation of blocks
15	RTK station details
16	RTK observation - measurement
57	RTK antenna height

Users can enter text for each measurement (observation 09 record or position 08 record) which is appended to the end of the record and this is used as the text of blocks that are interpreted according to the descriptions given in the earlier section “Field Coding for Non Leica Instruments” .

The '13' record can also be used after a measurement record to add additional information to the preceding blocks using the *extra coding* control code at the end of the previous line (see “Extra Coding” in the section “Control Code Blocks”

Strictly speaking the Sokkia SDR20/33 formats use fixed length lines and if the lengths are incorrect, an error message will be written to the Output Window. For example,

'Line 248 line incorrect length. required length is 58. received length is 50.'

These messages often appear after a raw file has been manually edited because most editors remove space padding at the end of a line.

To ignore such error messages, there is a setting *Allow bad line lengths* on the *Advanced* tab of the *Survey.4d Create/Edit* panel. If this is set for a data collector, then lines of incorrect length will not

be rejected.

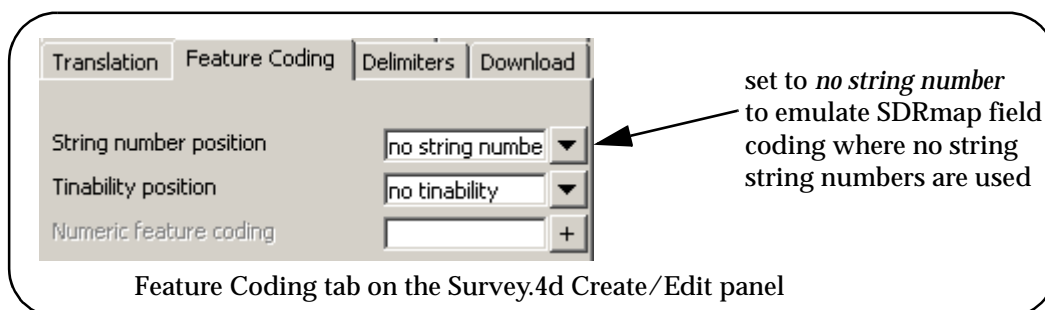

Advanced	Upload	Instrument	V4 Columns
Comment raw files			<input type="checkbox"/>
Report header			<input type="checkbox"/>
Allow bad line lengths			<input type="checkbox"/>
Verbose			<input type="checkbox"/>
Allow point numbers as stations			<input type="checkbox"/>

For non SDRmap users, please proceed to the section “Example of Sokkia SDR File” .

SDRmap users, please continue to the next section “Special Notes for SDRmap Users” .

Special Notes for SDRmap Users

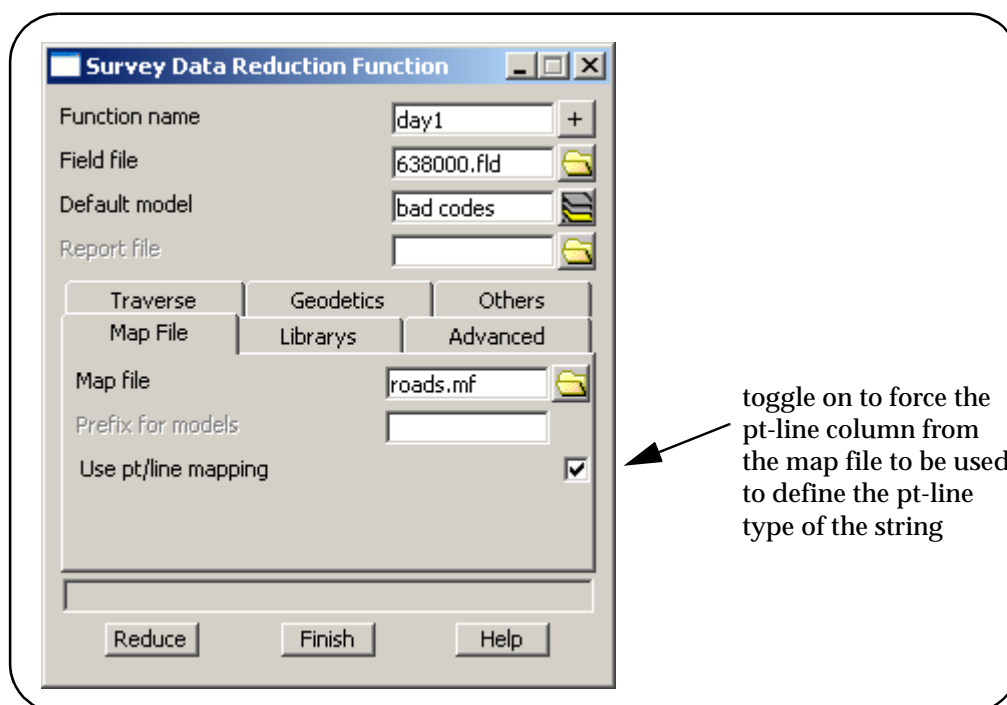

SDRmap does not use String numbers - only Feature codes are used and a *New String* command to denote the start of a new string. 12d Model supports only using a Feature code by setting the *String number position* on the *Feature Coding* tab to 'no string number'.

If *no string number* is set for the data collector (and so no string numbers are used in the field), then there is no way of telling from the field data whether the string is a *point* string or a *line* string (setting the pt-line type for the string).

For the *no string number* case, the method of defining the point-line type is to:

- (a) use a map file during the reduction
- and
- (b) have a key in the map file to match the feature code *and* have the pt-line type set for that key. If the *feature code* does not match any key in the map file, the string defaults to a *point string*.
- and
- (c) because by default the pt-string column in the map file is *ignored* during reduction (the string number usually defines the pt-line type), the *Use pt/line mapping* tick box in the Survey Data Reduction Function panel must be set to tick to *force* the pt-line column in the mapping file to be used.

Please continue to the next section "Example of Sokkia SDR File" .

Downloading SDR File To 12d

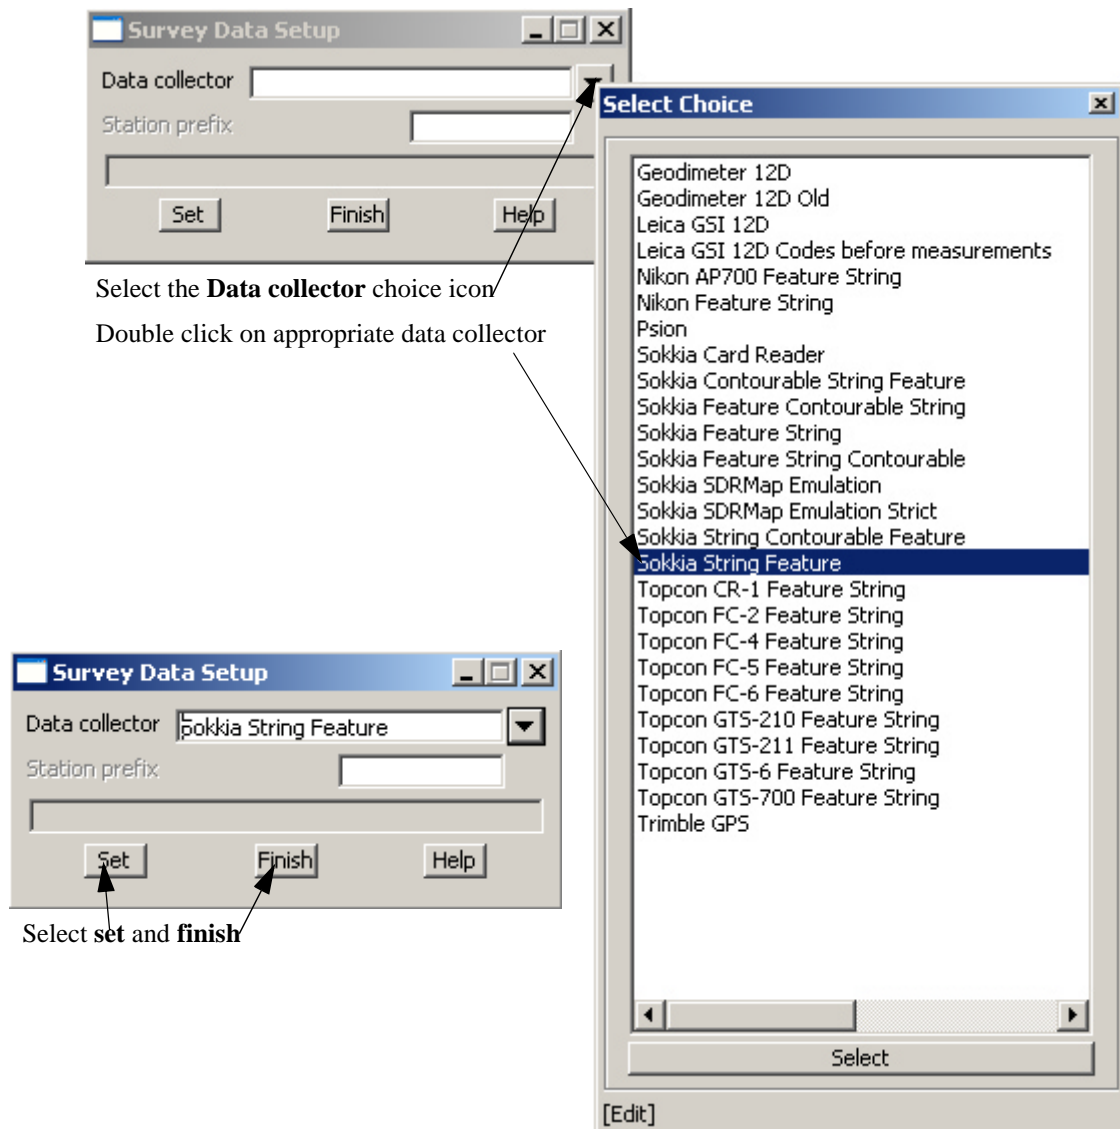

Raw SDR files can be input to 12d for reduction by two basic methods:

1. Download directly from the instrument
2. Copy the SDR file to the working folder directly from a PCMCIA card or by using a data transfer product such as "HyperTerminal" or "Wincomms" etc. For this method, see the following section "Converting SDR Raw File To Field File" .

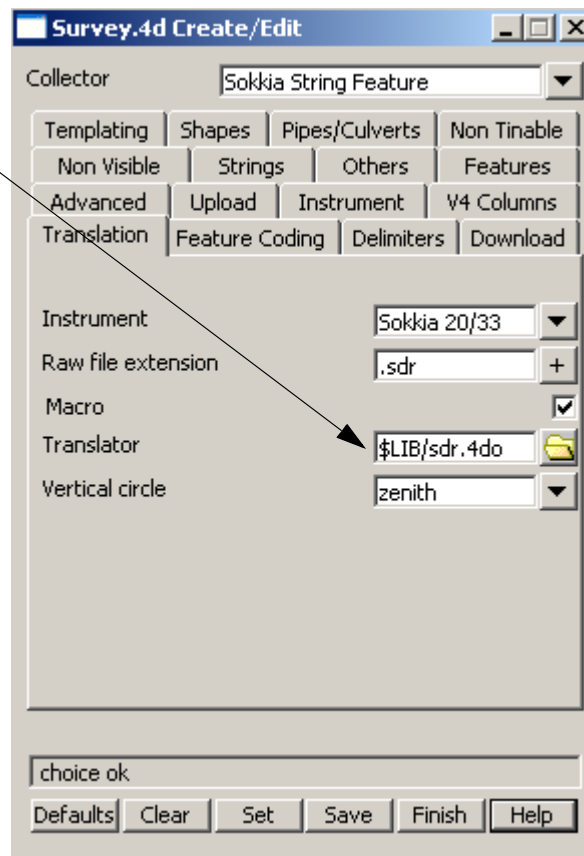

An option exists within 12d to download the raw SDR file from the instrument. This option has the added functionality that it reduces the raw propriety format (SDR file) to a 12d field file format at the same time. This conversion requires that the data collector definition be set before the download of the file is commenced.

Select the data collector type

Select option *Survey=>Setup*

The raw file will be converted to the 12d field file format using the specified translator macro

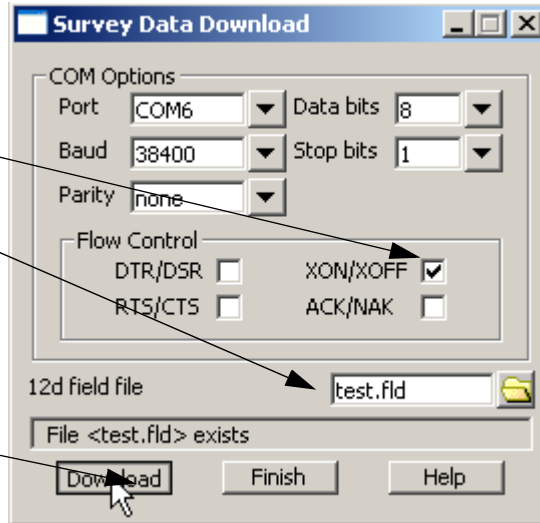

Select *Survey=>Download*

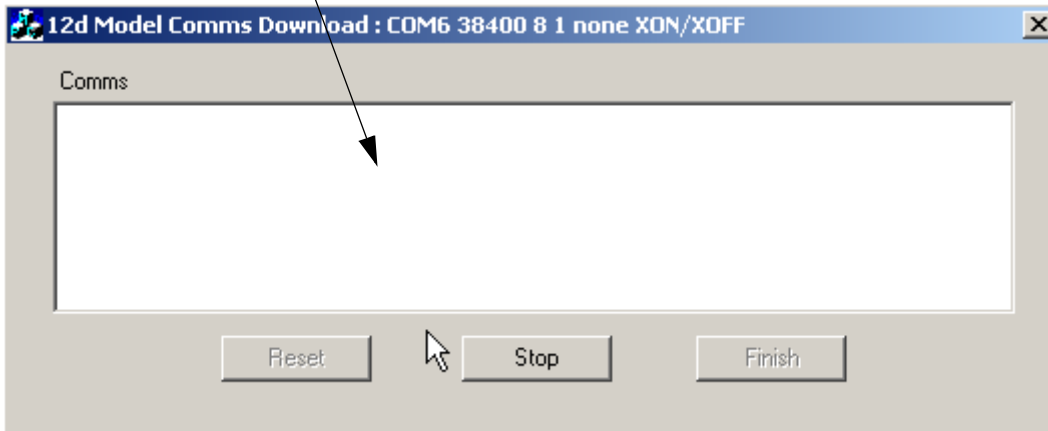

Ensure that the correct values are set for the comms settings i.e. they match the data collector parameters

Enter a name for the field file

Press **download**

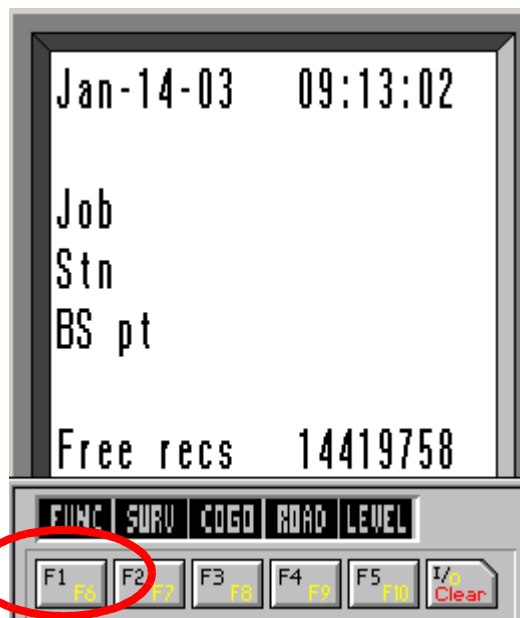

The 12d download window is shown.

Prepare the data collector for download by connecting to appropriate port, selecting file to download etc.

From the Data collector main menu select the **FUNC** (function) menu

Toggle down to the
Communications menu

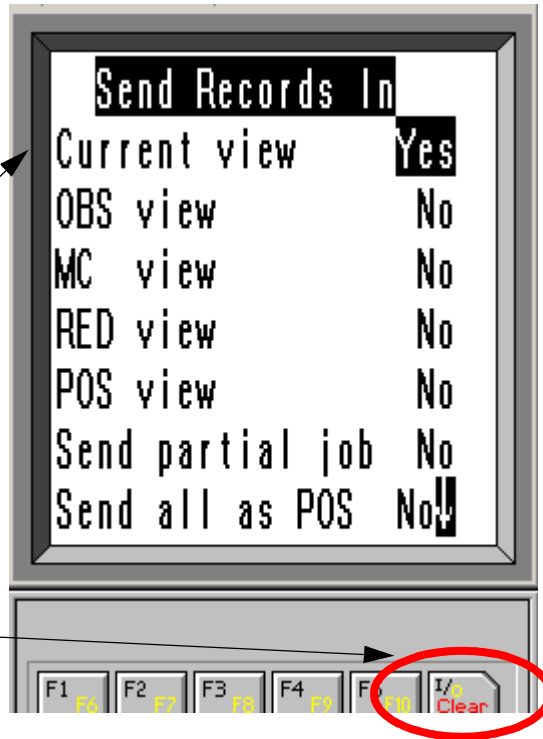

Press **OK** to select
menu

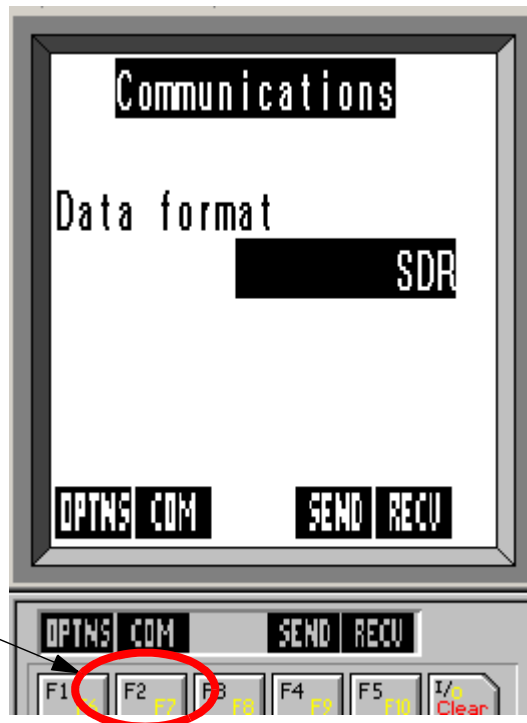

Select the **Options**
menu to view the
current settings

Select the **Current view** to **Yes** only. If the POS view were set to **Yes** also, the POS points would be sent also and eventually reduced twice in 12d (once from observations and the other from the POS record). Press **Clear** to leave menu

Select the **COM** menu to view the current comms settings

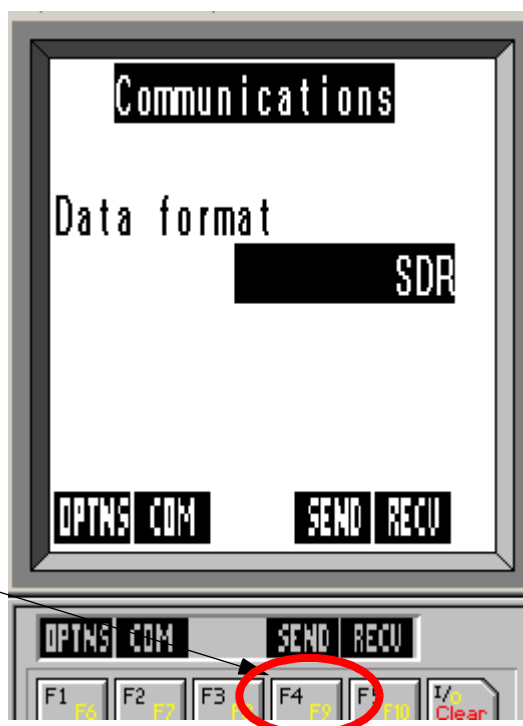

Ensure the comms settings are as per the values set in the 12d download option.

Select **Clear** to leave the menu

Select the **SEND** menu

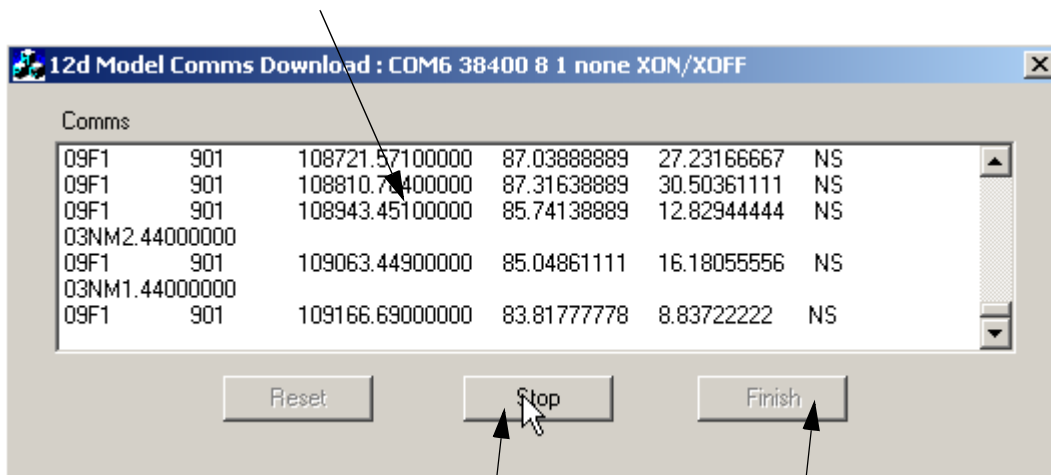

Select the file to download

Press OK to send

The file is shown downloading line by line in the 12d download window.

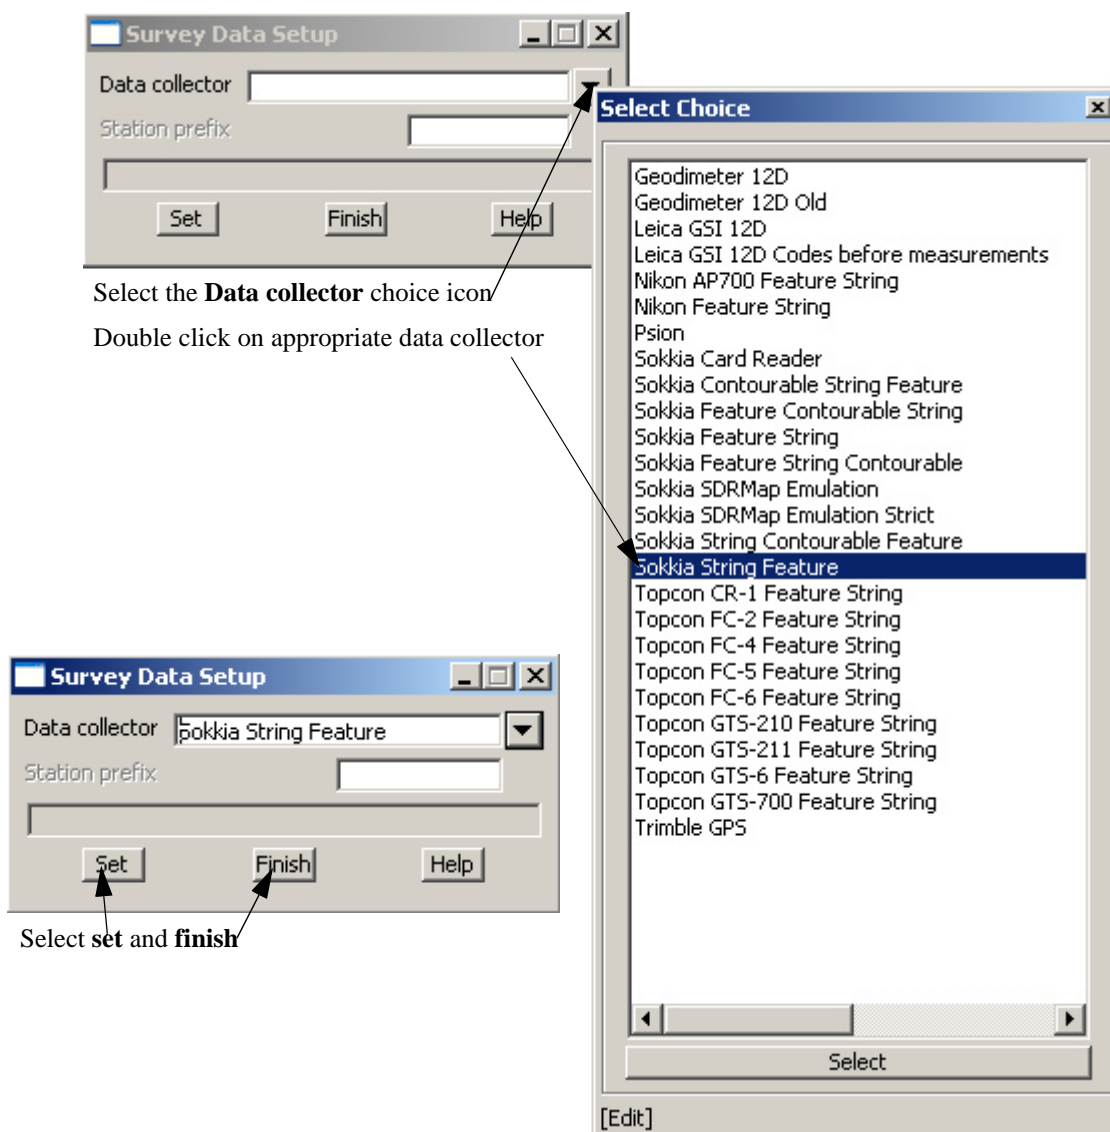

When the download is finished select the **stop** button and then **finish**

Converting SDR Raw File To Field File

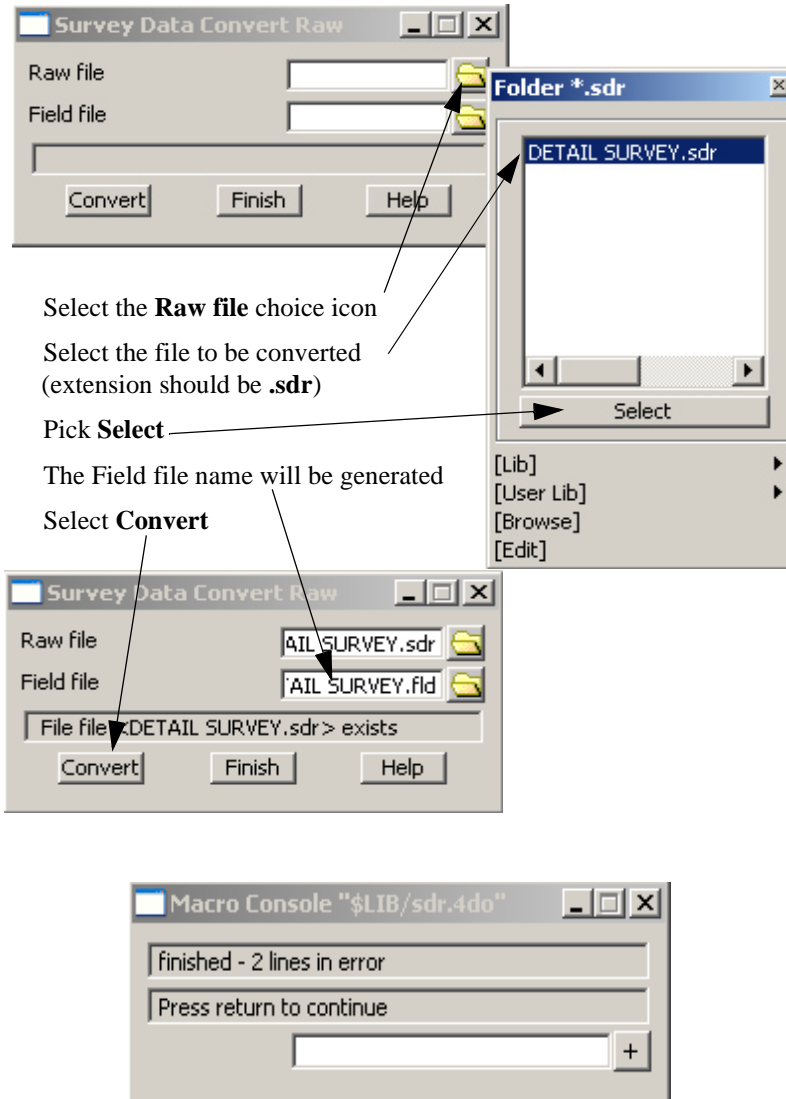

If a raw SDR file is copied to the working folder from a PCMCIA card or other means such as transferring it from a third party software package, it must be converted to a 12d field file for reduction inside 12d.

Select the data collector type

Select option *Survey=>Setup*

Select option *Survey=>Convert raw*

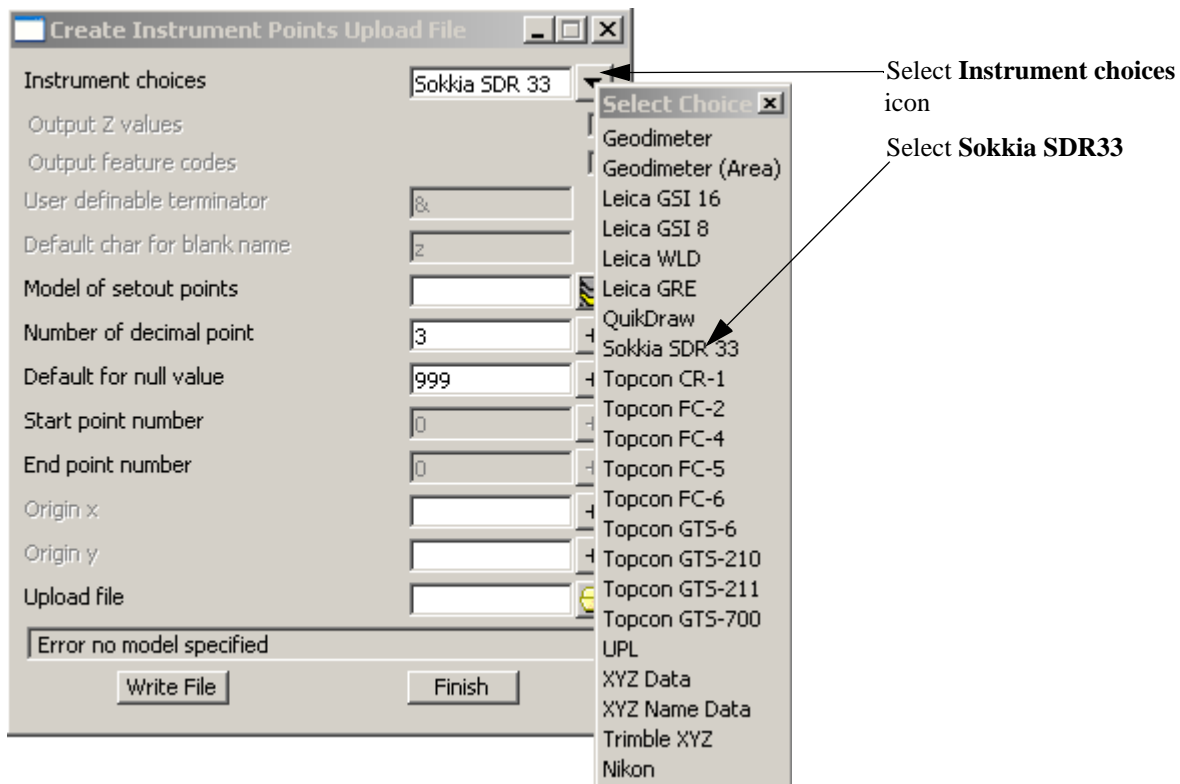

Any errors will be listed in the Output window. If the Output window is not shown, it can be opened using the option **Window=>Output Window**

Creating SDR Point Upload File

Create upload file in 12d

After creating the setout points an upload file can be created for the sdr format

Select option *Survey=>Upload=>Create points upload file*

Fill in the rest of the screen as per normal

Select **Write File**

A SDR33 file is created ready to send to the instrument directly using the upload facility or by copying the file to PCMCIA cards etc.

Loading file into controller using 12d upload facility

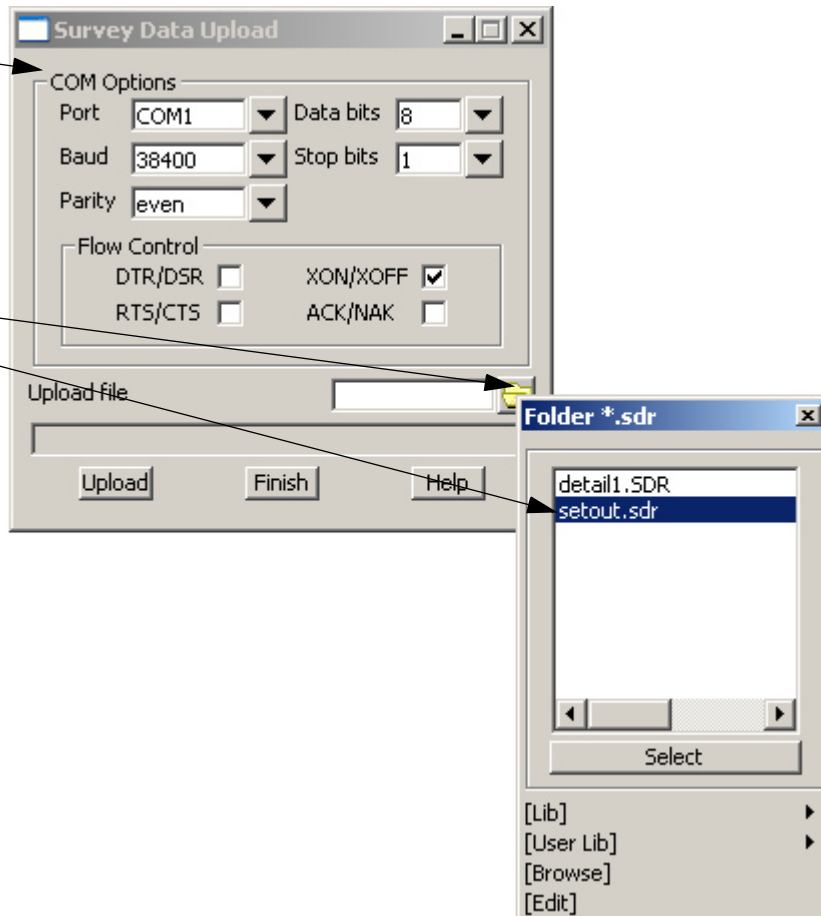

The points upload file can be transferred to the controller for setout using the upload panel.

Connect the controller to the PC

Select option *Survey=>Upload=>Upload*

Ensure that the correct values are set for the comms settings i.e. they match the data collector parameters

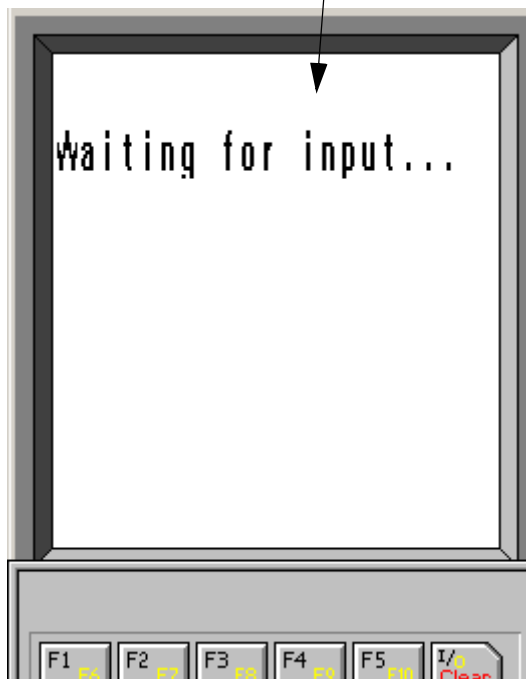

Select the upload file by selecting the folder icon and selecting the appropriate file

Prepare the data collector for uploading.

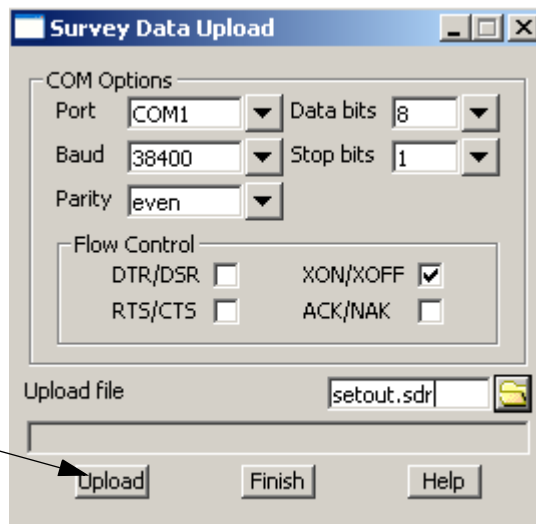

From the communication menu, select the receive button

Once the data collector is ready, the data can be sent from 12d

Select **upload** to start uploading the file

Creating SDR Roads Upload File

Create upload file in 12d

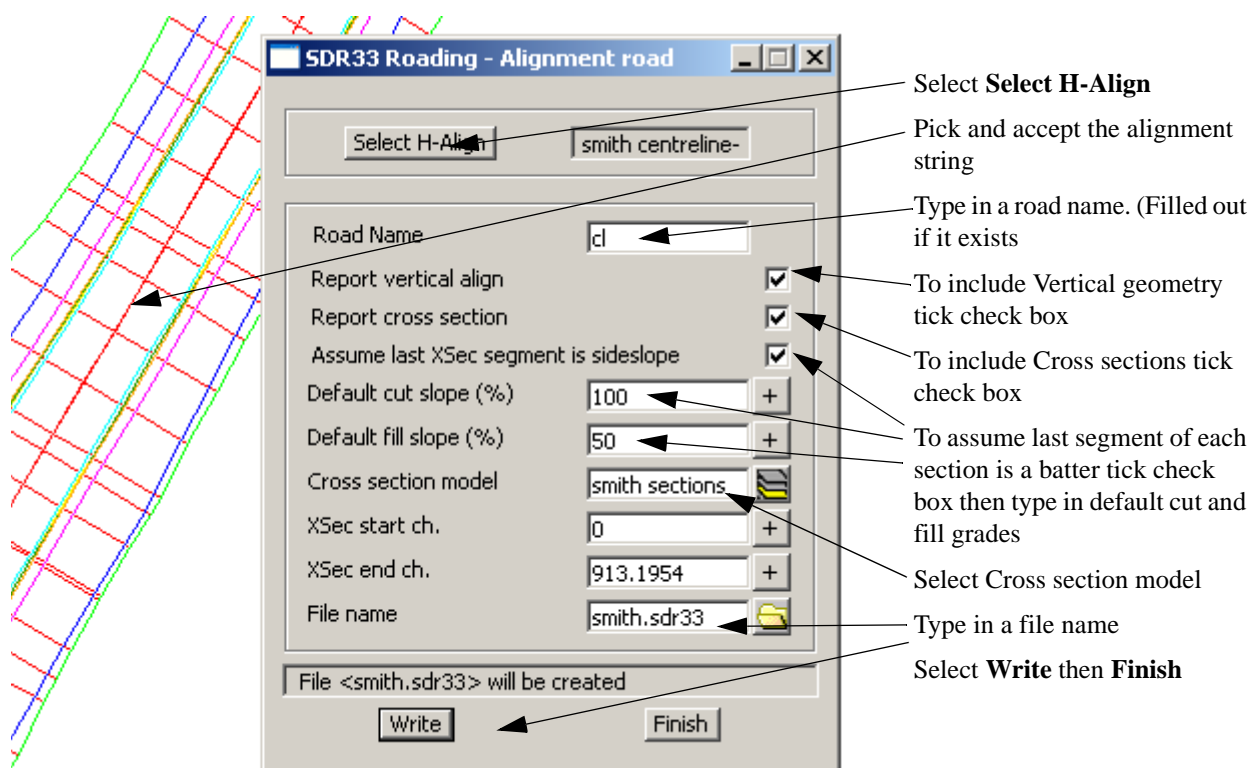

After creating the road alignment an upload file can be created for the SDR33 format

Select option *Survey=>Upload=>Create roads upload file*

Select **Instrument** choice icon

Select **Sokkia Roding - Alignment Road**

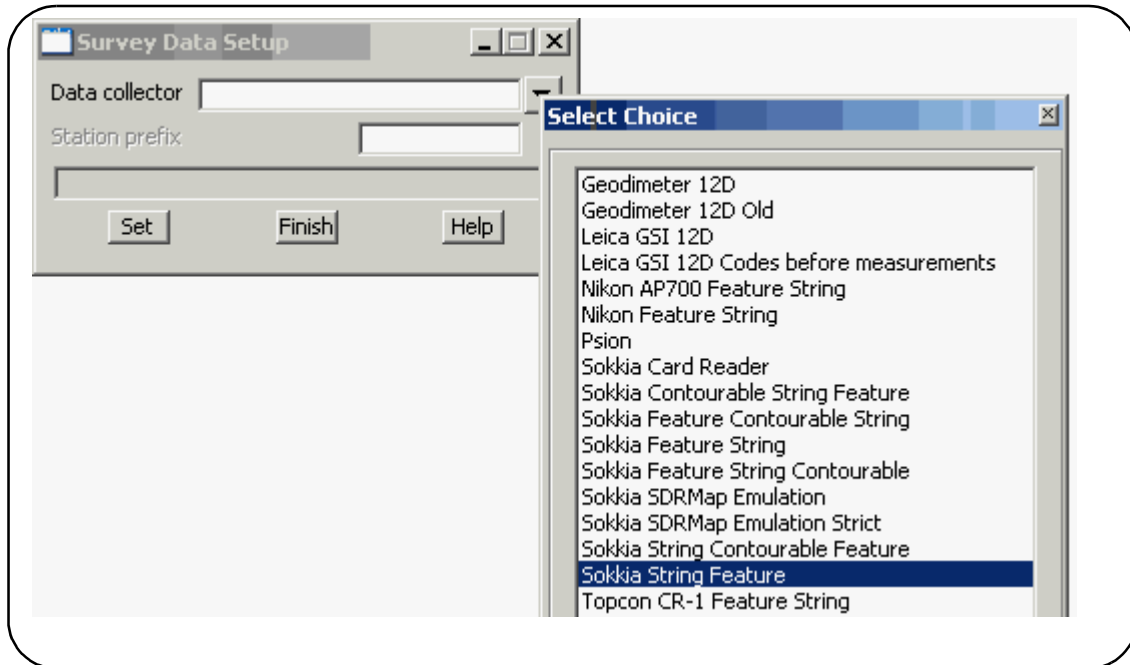

A SDR33 file is created ready to send to the instrument directly using the upload facility or by copying the file to PCMCIA cards etc. The steps involved in uploading the file to the controller using the 12d upload facility can be seen in the previous section “Loading file into controller using 12d upload facility” on page 3172.

Example of Sokkia SDR File

The raw Sokkia SDR file 'detail1.sdr' has been coded in accordance with the data collector definition *Sokkia String Feature* which is shipped with 12d Model.

The data collector *Sokkia String Feature* is set using the option *Survey=>Setup*

Translation	Feature Coding	Delimiters	Download	Non Visible	Strings	Others	Features
Command		*		Close			C
Comment				Rectangle			R
Offset code		.		Rectangle by 2 pts			
String		+		Start arc fitting			S
Backsight		BS		End arc fitting			E
Foresight				New string			ST
Check measurement		CHK		End string			
Extra coding		X					

Non Visible	Strings	Others	Features
by radius			
by diameter			

Templating	Shapes	Pipes/Culverts	Non Tinable
Invert			I
Obvert			O
Centre			A

Templating	Shapes	Pipes/Culverts	Non Tinable
Record			XA
Start			XB
End			XC
Pause			XD
Pause after			
Continue			XE
Skip			XF
Insert			
Delete			

Templating	Shapes	Pipes/Culverts	Non Tinable
Remove height			NH
Point			XP
Previous segment			XL
Next segment			XN

For the *Sokkia String Feature* data collector definition, the *string number* is given before the *feature code*.

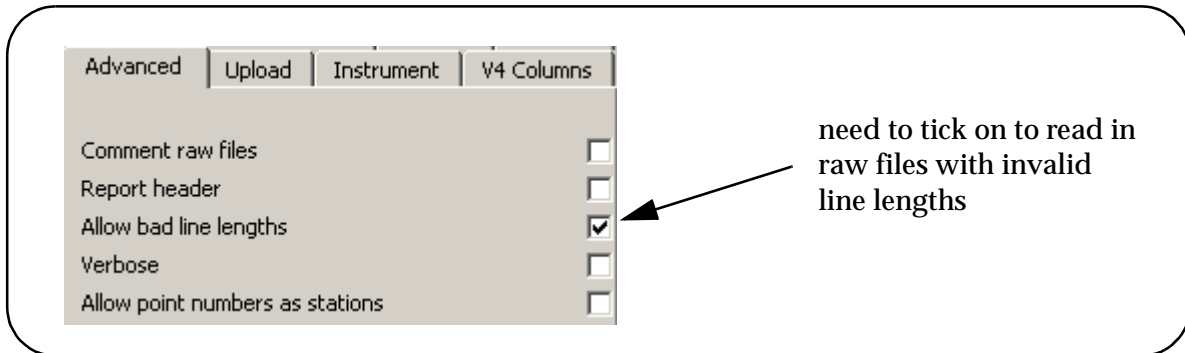

Some of the control codes defined for the *Sokkia String Feature* data collector that are used in the example are:

- * is used as the Command (Block) delimiter
- space is used as the comment delimiter
- S and E are used to start arc fitting and end arc fitting respectively
- R is the Rectangle (make a parallelogram) command
- the template commands XA, XB, XC and XD are used
- the invert I and obvert O commands are used.
- XN for the next segment to be non-tinable (that is, not a breakline).

The listing of the raw file 'Detail1.sdr' is now given, followed by a dump of a 12d Model view displaying the job. No mapping file has been used in the reduction so no line styles appear on

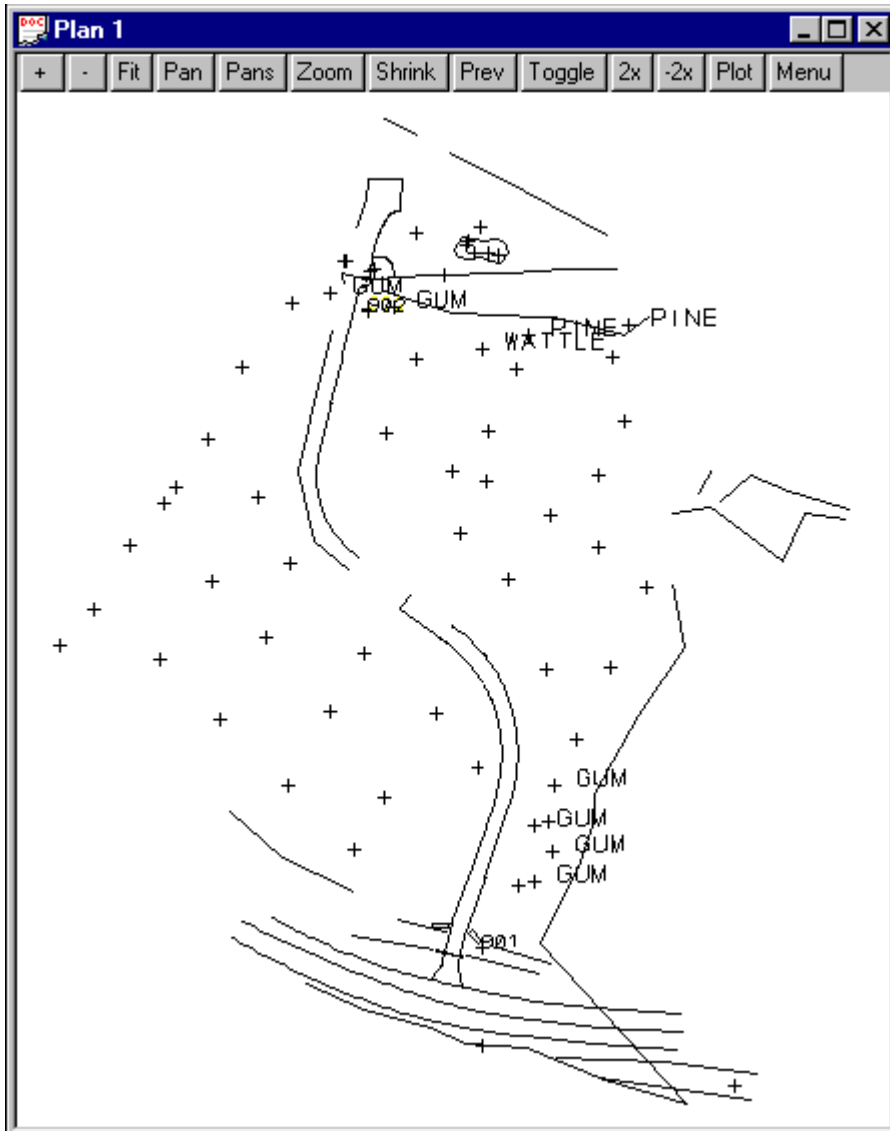

the view.

WARNING - The raw file 'Detail1.sdr' is in the Survey area of the training data but the file has been manually edited and if read in with the standard *Sokkia String Feature* data collector, will have bad line lengths and the data ignored. To read the file in, the *Allow bad line lengths* on the *Advanced* tab of the *Sokkia String Feature* data collector will need to be set before converting the raw file to a 12d field file.

C 12d and the Trimble Total Station ACU

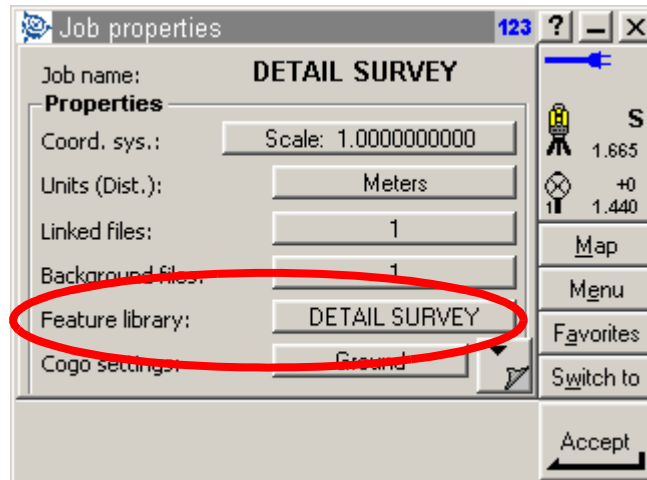

This Section deals with interfacing 12d with the Trimble Total Station ACU unit data formats

These notes are not meant to take the place of the operations manuals for the Trimble ACU but rather to act as a guide for ensuring the correct file types are used between the two systems.

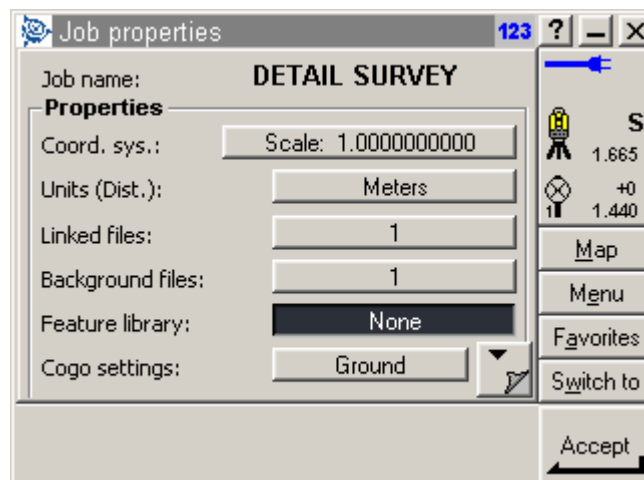

Coding

On the ACU the user can either manually type in a code for field readings or use a code library to pre-define codes which can then be selected from a list

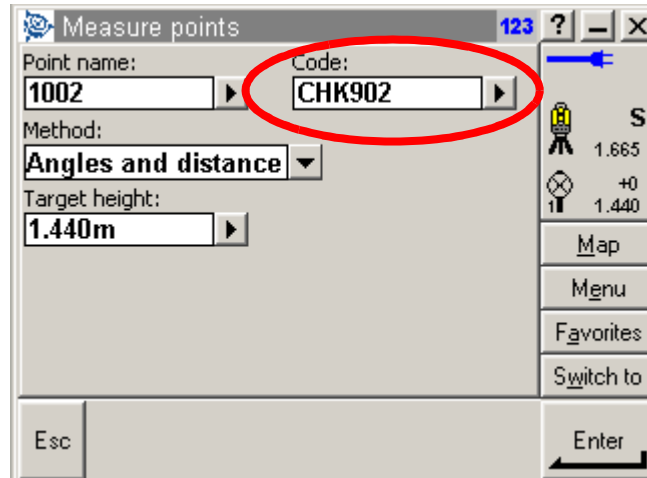

To use a code library the user should select the relevant library when creating the job

If using string numbers the Feature library can be set to *None* and the string number, feature code, field code and delimiters can be manually typed in

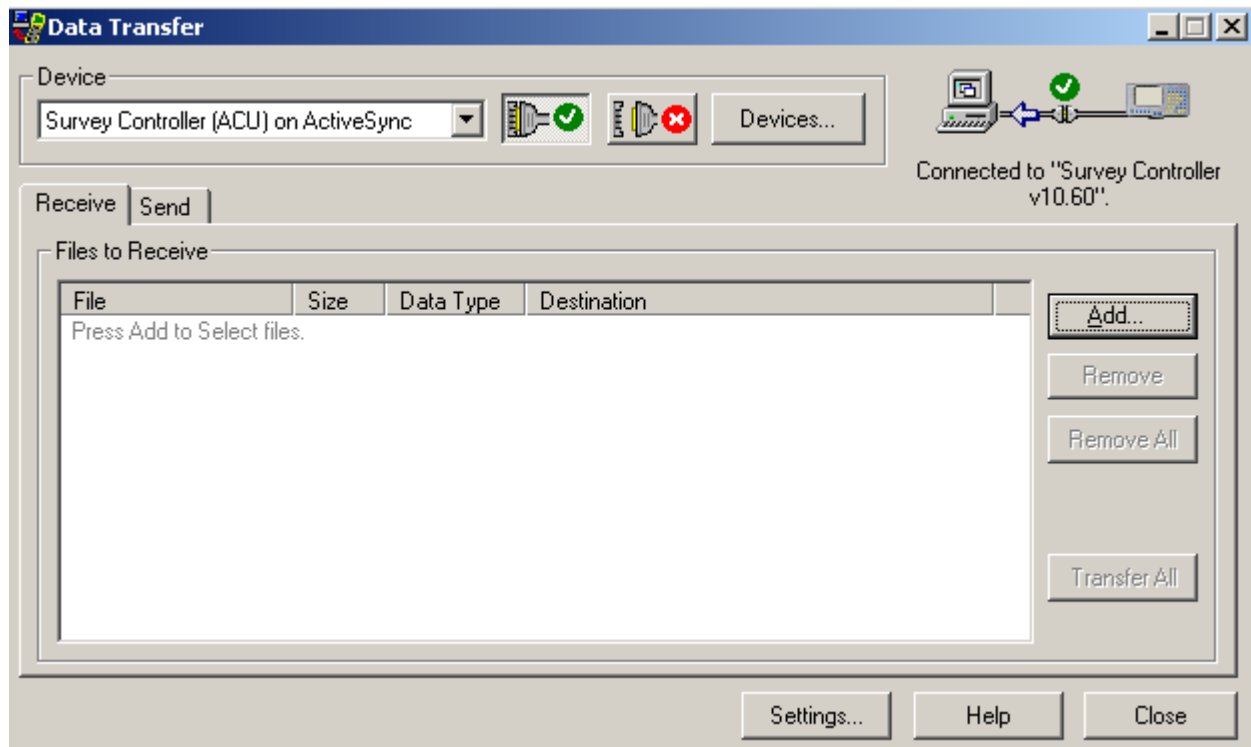

Codes are typed in to the ACU in the **MEASURE POINTS** option

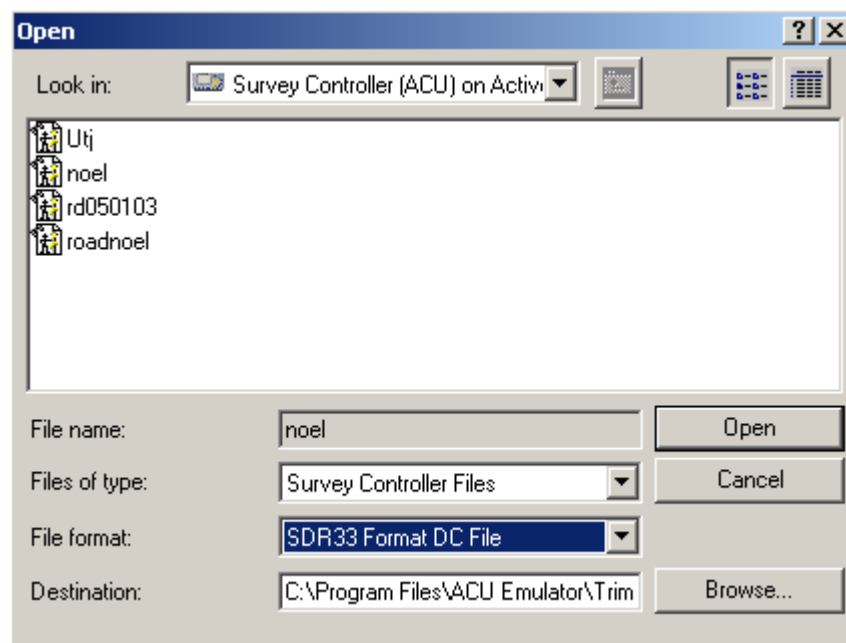

Sending Raw file to 12d

The raw file can be transferred from the ACU as a format similar to the SDR33. This is called the **SDR33 DC** file format.

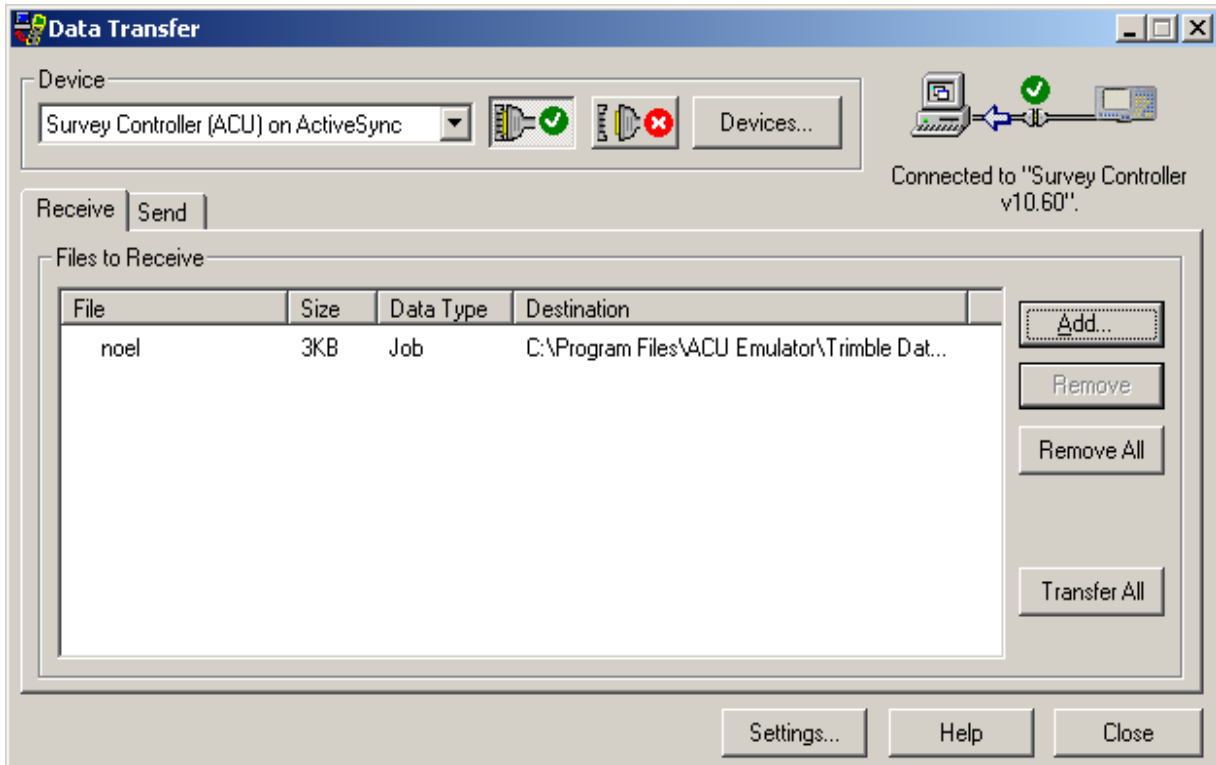

Connect the ACU to the PC using **TRIMBLE DATA TRANSFER**

Select **Receive** tab then select **Add**

Select the Job to download using the format **SDR33 FORMAT DC FILE**

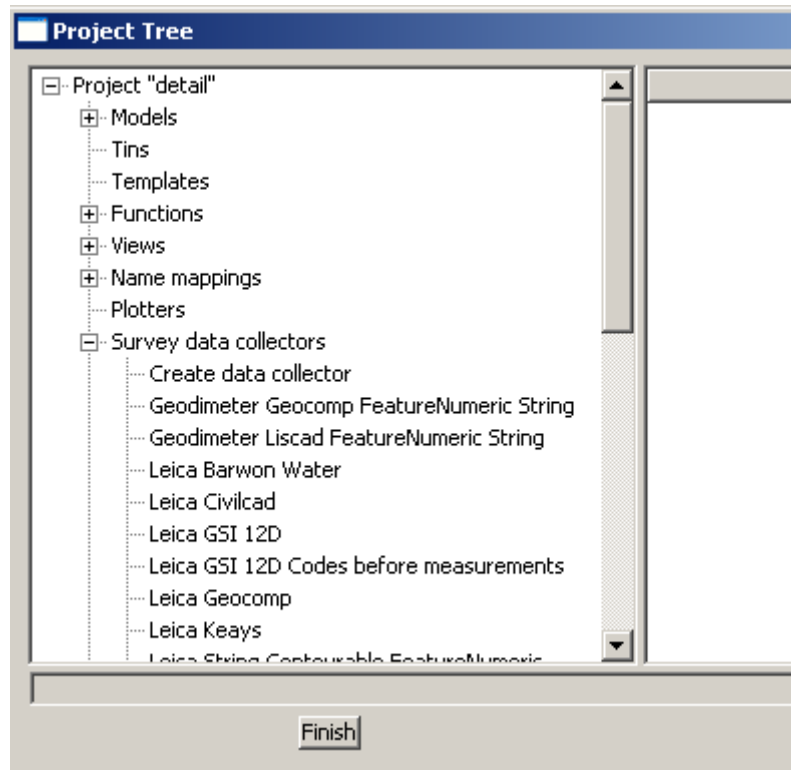

Select **Transfer All** to transfer the file

Converting raw file to field file

Create new data collector type

We will create a specific name for the Trimble data collector even though it is similar to the SDR33 format

Select **Project=>Browse**

Select the Survey data collectors branch

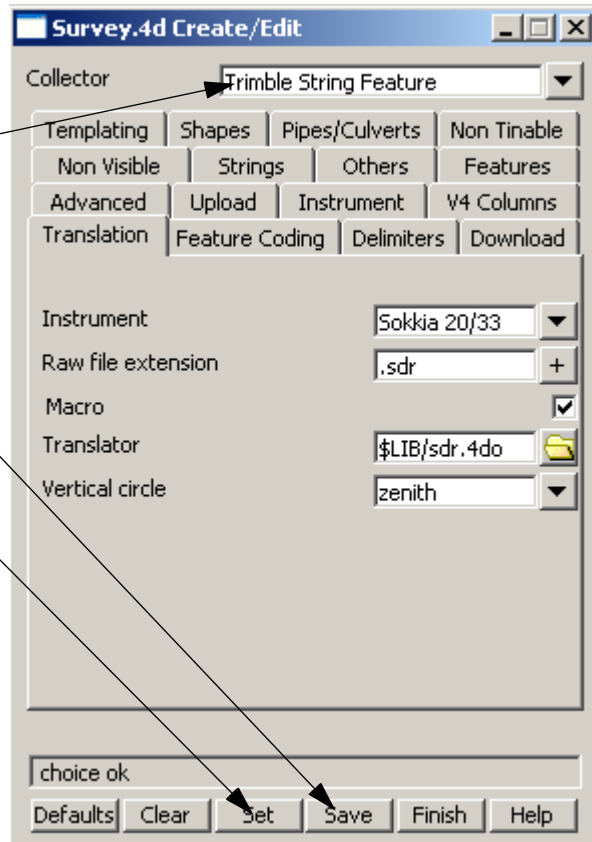

Double click on **Sokkia String Feature**

- Sokkia Keays
- Sokkia SDRMap Emulation
- Sokkia String Contourable Feature
- Sokkia String Feature
- Topcon FC5 Feature String
- Topcon GT700 Feature String
- Ubisut

This loads up the default parameters for the SDR33 format.

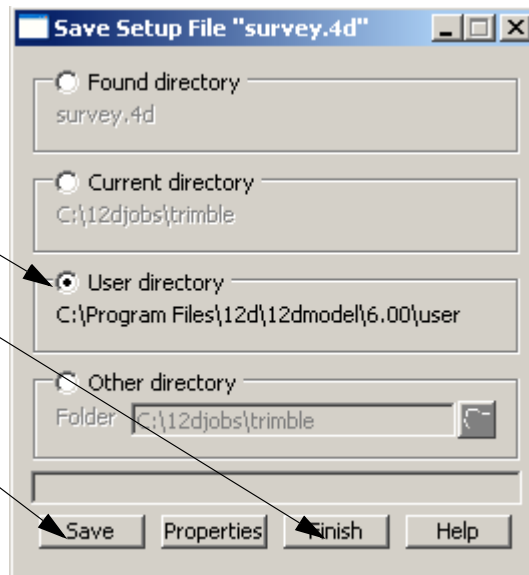

Type in the new name **Trimble String Feature**

Select **Set** then **Save**

Select **User directory**

Select **Save** then **Finish**

Select **Finish** back in the previous panel

To set the changes the project has to be restarted by selecting **Project=>Restart**

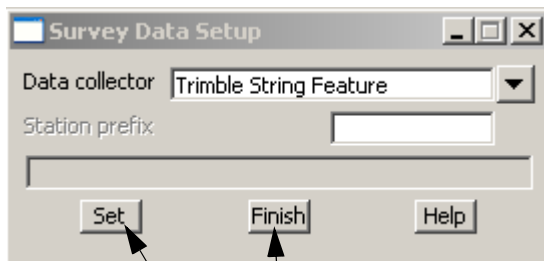

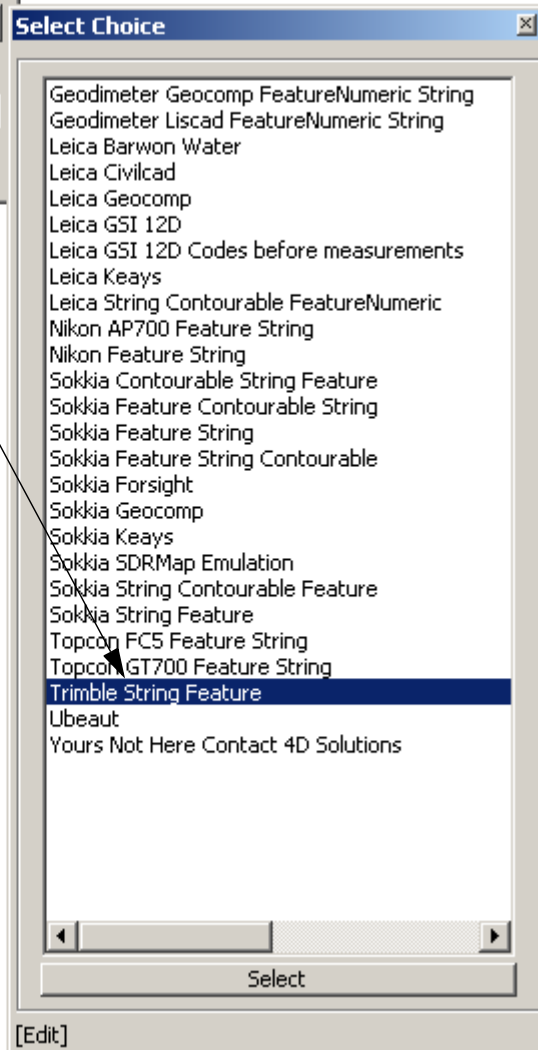

Select the data collector type

Select option *Survey=>Setup*

Select the **Data collector** choice icon

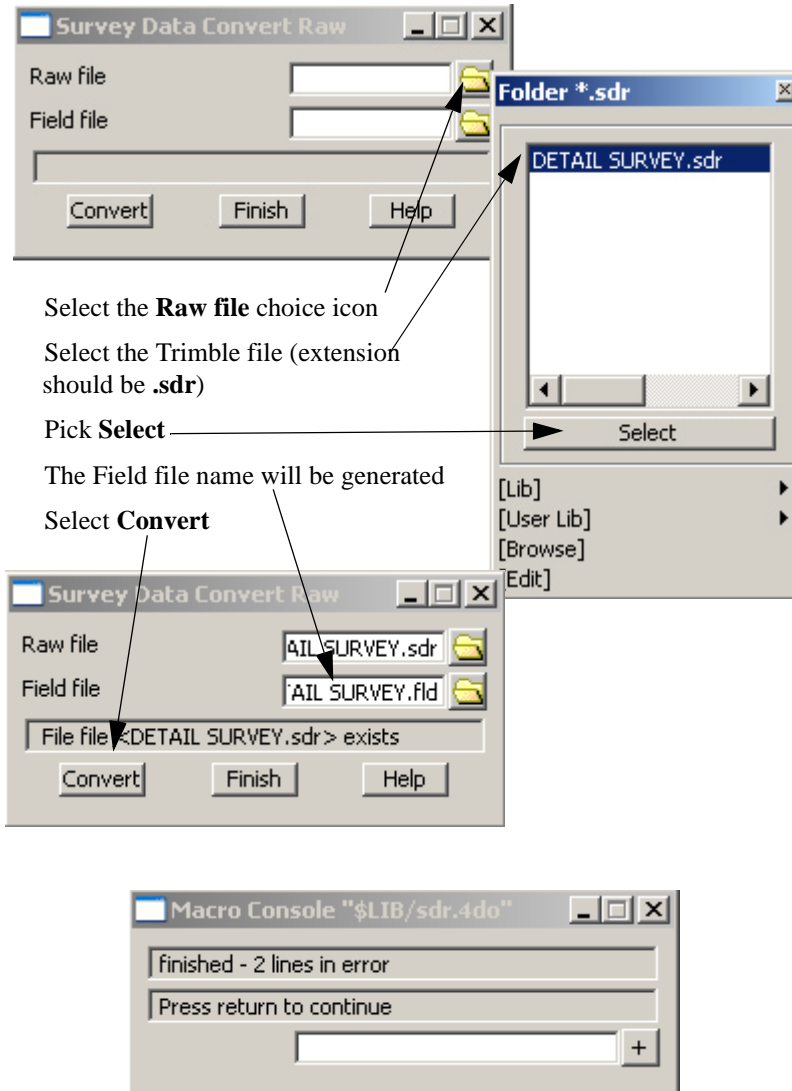

Double click on **Trimble String Feature**

Select **Set** then **Finish**

Convert raw file

To convert raw file to field file select option *Survey=>Convert raw*

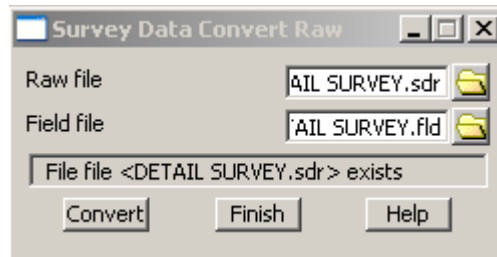

Any errors can be listed by opening the Output window using option *Window=>Output Window*

```
format = sdr33
Line 7 command not implimented <05NM          >
Line 8 non supported derivation code <02      901  5000.0000000000001000.000000000001(
Line 14 command not implimented <05NM        >
Line 15 non supported derivation code <02     901  5000.0000000000001000.000000000001
```

Close the Error panel

Select **Finish**

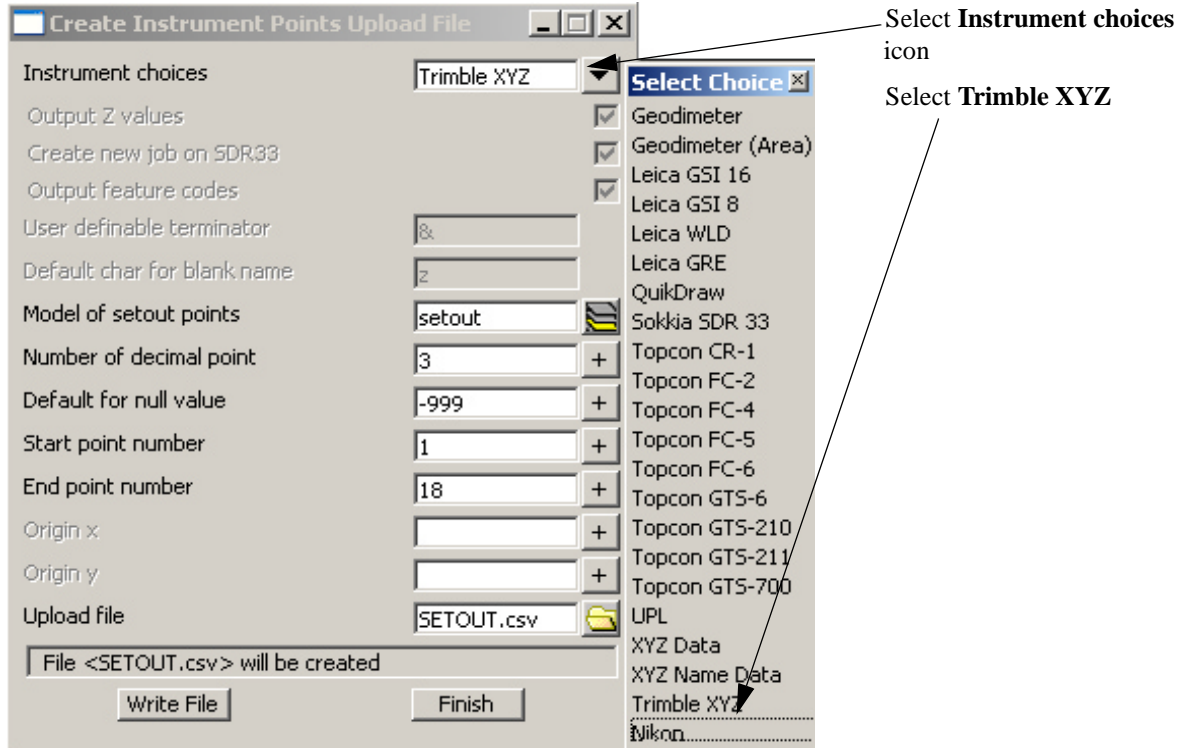

The field file can now be reduced in the normal manner

Creating point upload file

Create upload file in 12d

After creating the setout points an upload file has to be created for the trimble format

Select option *Survey=>Upload=>Create points upload file*

Fill in the rest of the screen as per normal

Select **Write File**

A standard comma delimited file is created ready to send to the ACU

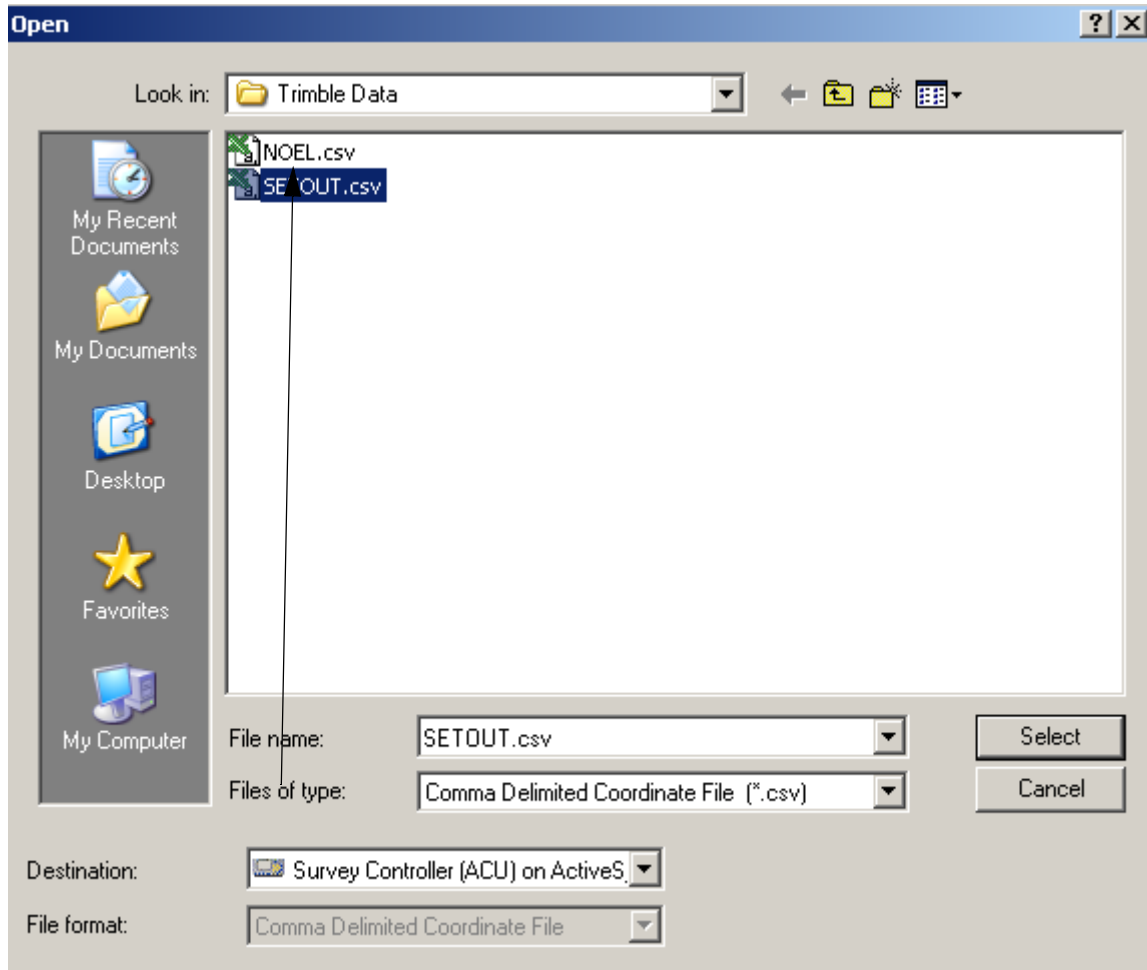

Loading file into job in ACU

The points upload file can be transferred to the ACU for setout.

Connect the ACU to the PC using **TRIMBLE DATA TRANSFER**

Select **Send** tab then select **Add**

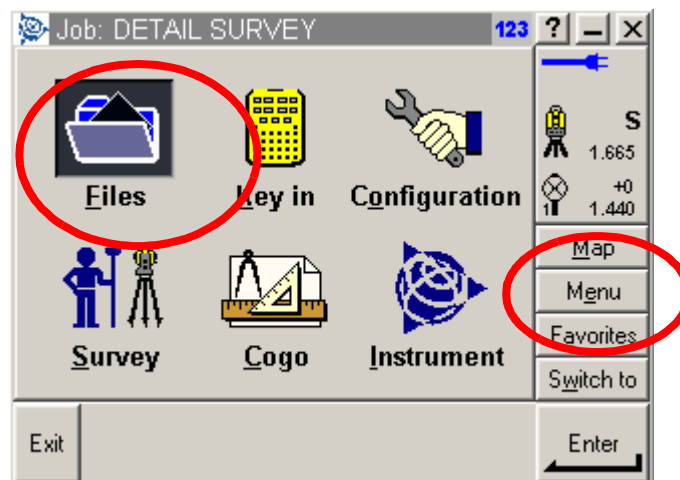

Select the file to upload using format *Comma delimited coordinate file*

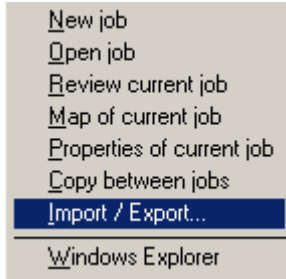

Select *Transfer All* to transfer the file

To load the file into the current job on the ACU select *Menu=>Files*

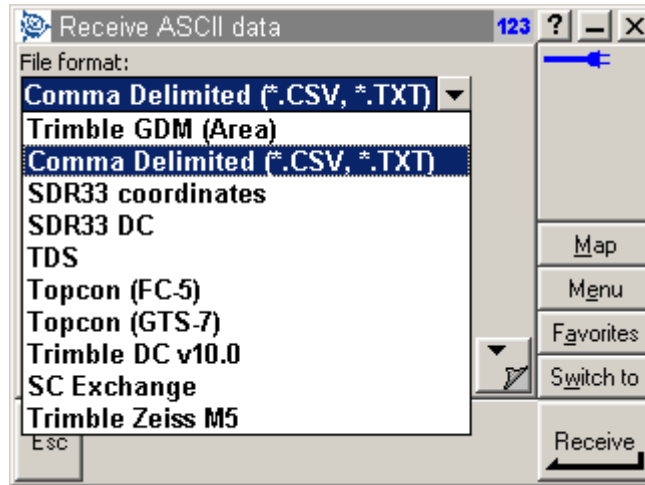

Select *Import / Export*

Select **Receive ASCII data**

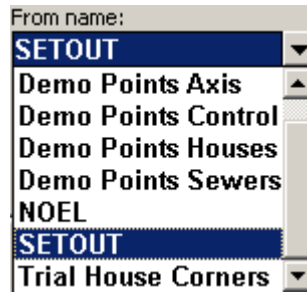

Select **File format** choice icon then pick **Comma Delimited (*.CSV, *.TXT)**

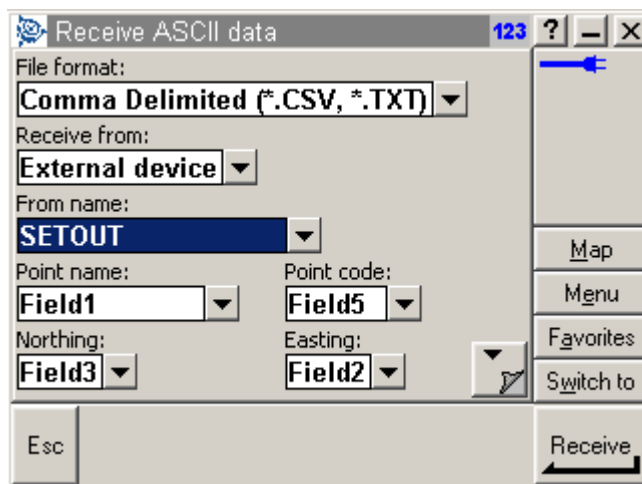

Select **Receive from** choice icon and pick **Trimble Data**

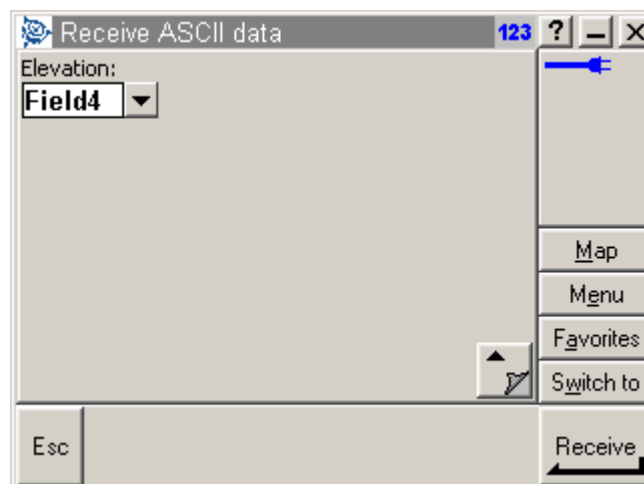

Select **From file** choice icon and select file

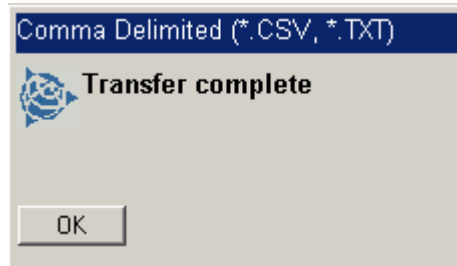

Select the field order for the file as (1) Point number, (2) Easting, (3) Northing, (4) Level and (5) Code

Select the **Next page** icon

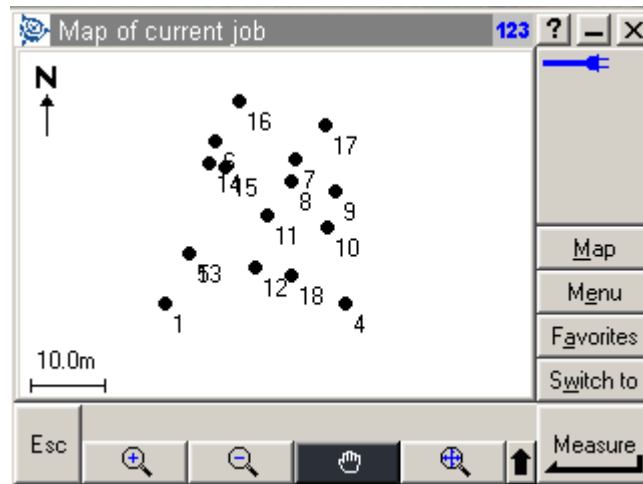

Select **Receive**

Select **OK** to finish

The points can be displayed by selecting **Map** and zooming all of the job

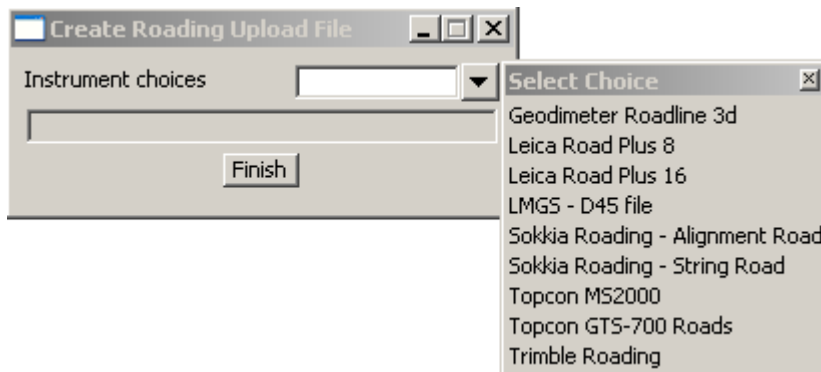

Create Roads upload file

Create upload file in 12d

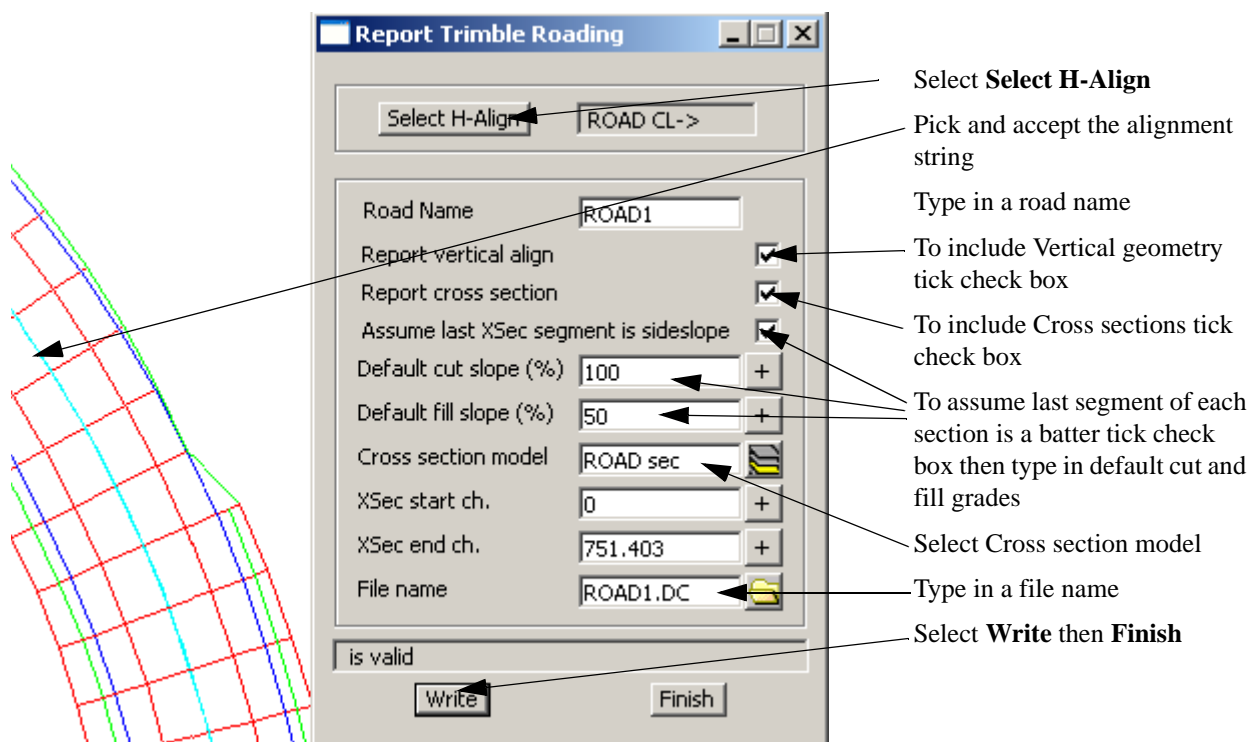

After creating the road alignment an upload file has to be created for the trimble format

Select option *Survey=>Upload=>Create roads upload file*

Select **Instrument** choice icon

Select **Trimble Roding**

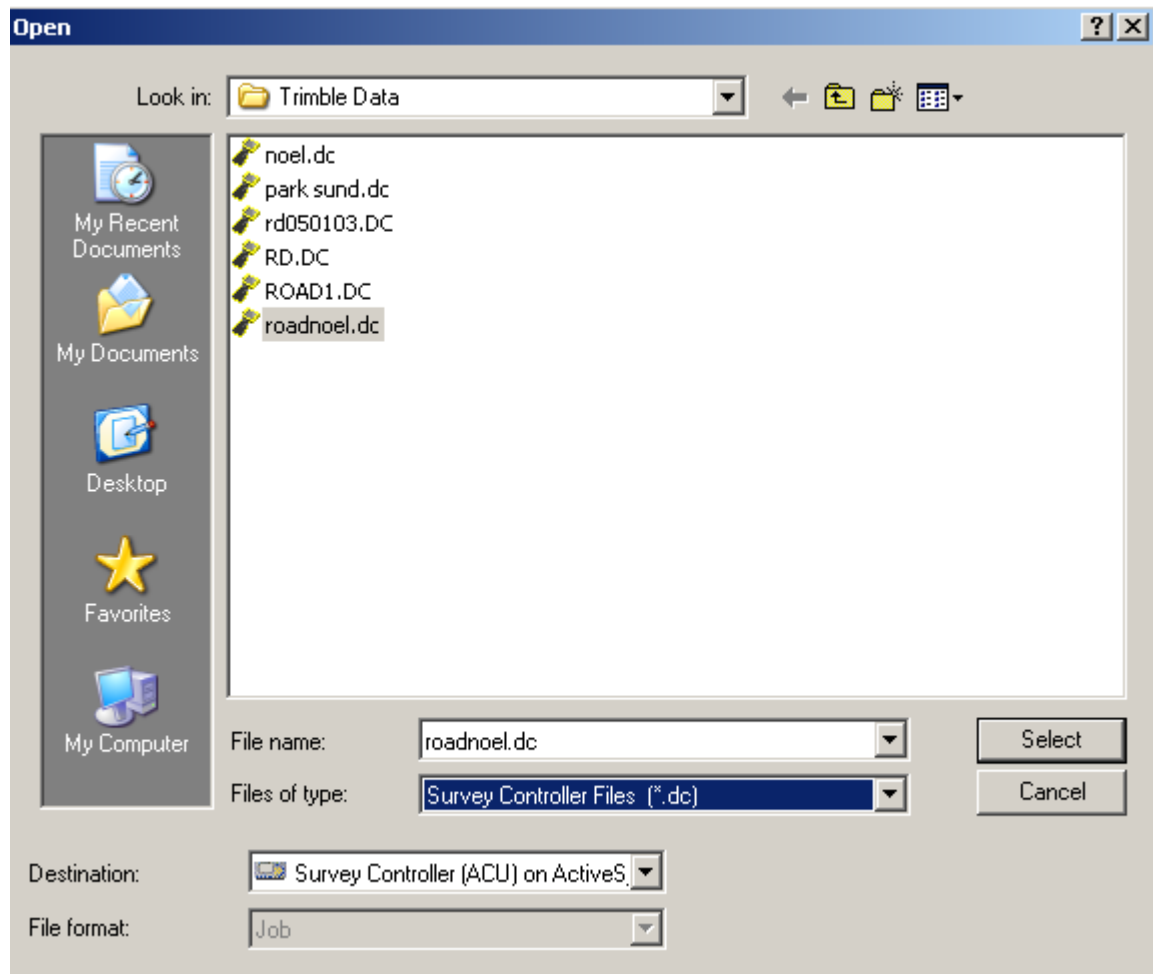

Loading file to the ACU

The road upload file can be transferred to the ACU for setout.

Connect the ACU to the PC using **TRIMBLE DATA TRANSFER**

Select **Send** tab then select **Add**

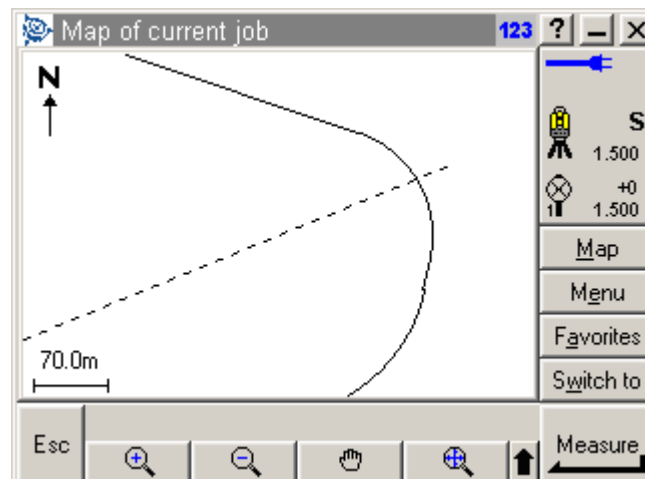

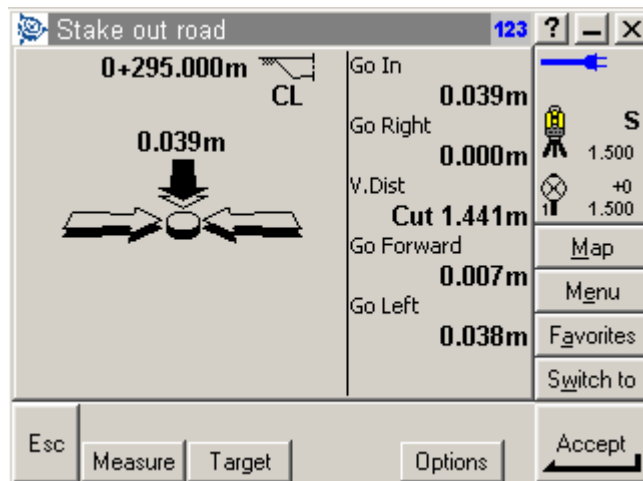

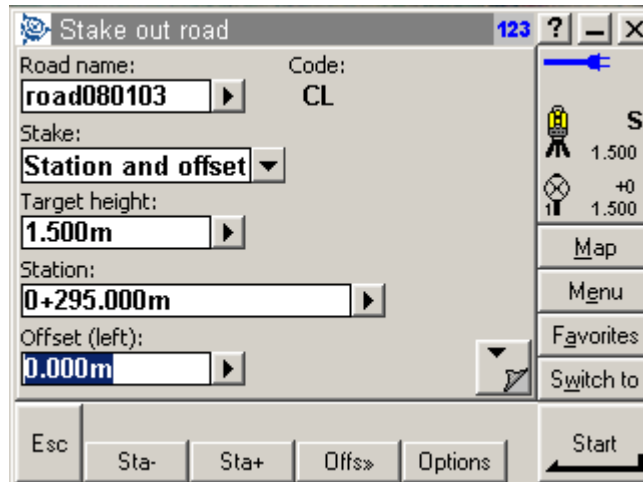

Select the road file to upload using format *Survey Controller file*

Select **Transfer All** to transfer the file

Once the road file has been copied into the ACU it can be setout using option **Survey=>Stakeout=>Roads**

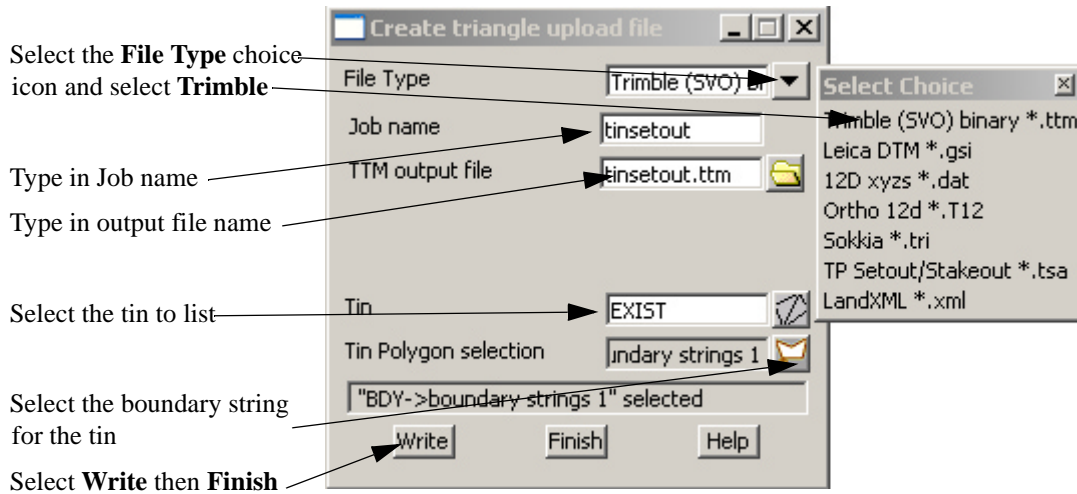

Create Tin upload file

Create upload file in 12d

After creating the triangulation an upload file has to be created for the trimble format

Select option *Survey=>Upload=>Create triangle upload file*

Select **Yes** to create the file

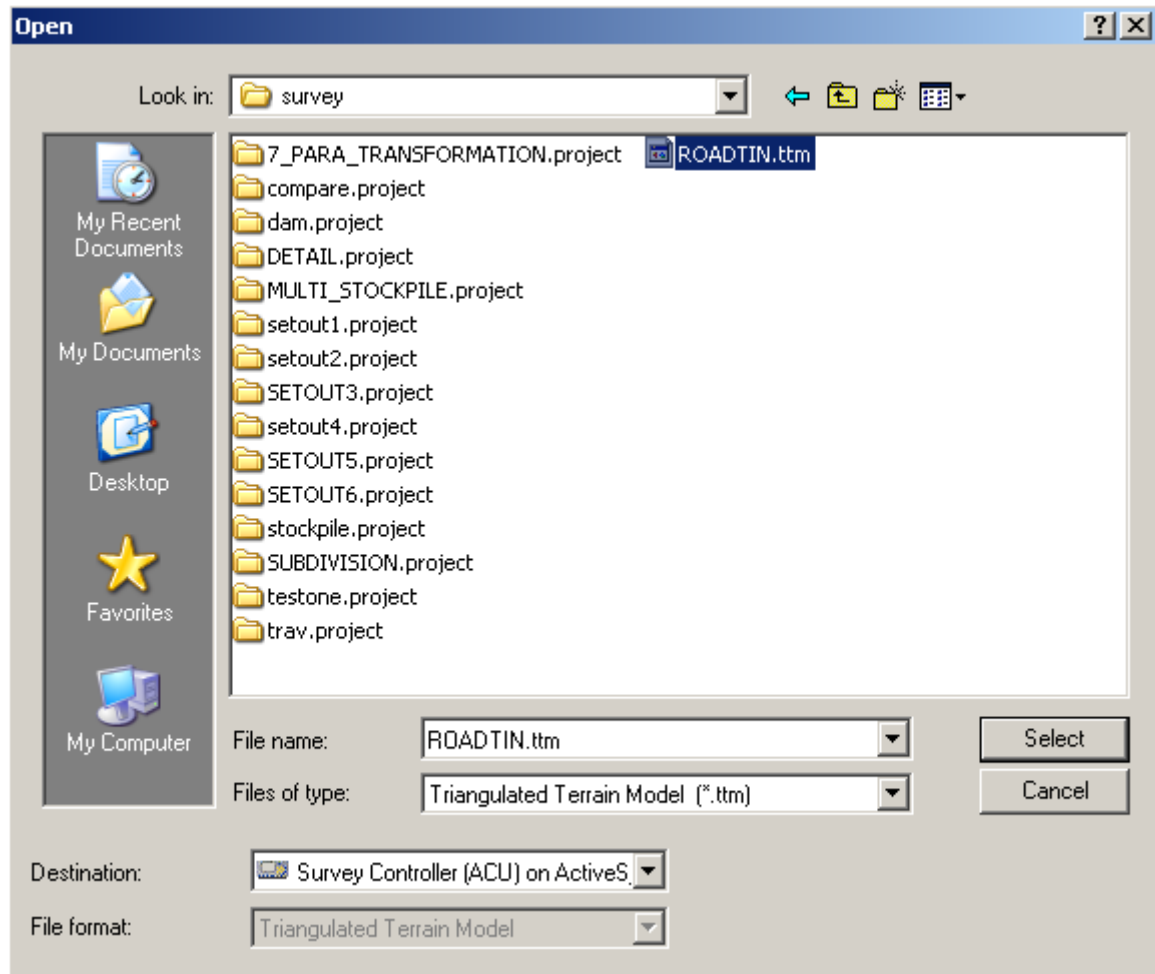

Loading and using the file in the ACU

The tin upload file can be transferred to the ACU for setout.

Connect the ACU to the PC using **TRIMBLE DATA TRANSFER**

Select **Send** tab then select **Add**

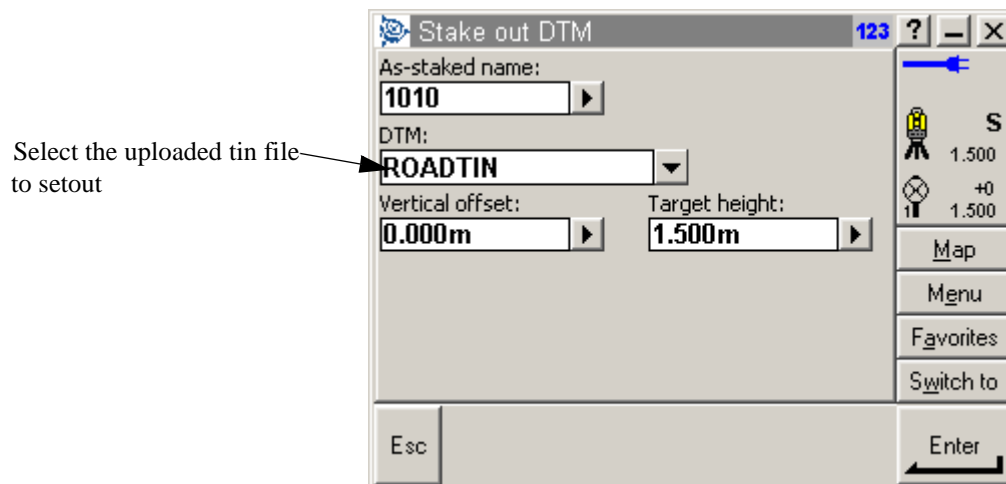

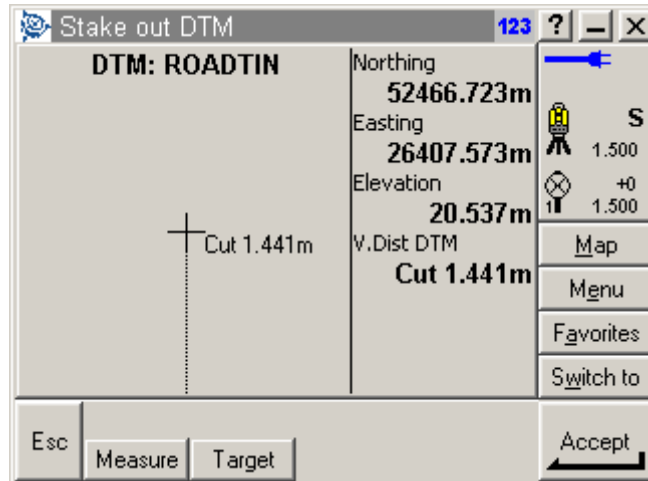

Select the tin file to upload using format *Triangulated Terrain model*

Select **Transfer All** to transfer the file

Once the tin has been copied into the ACU it can be called up when using the Stakeout option
Survey=>Stakeout=>DTM

The cut to the tin is calculated and displayed

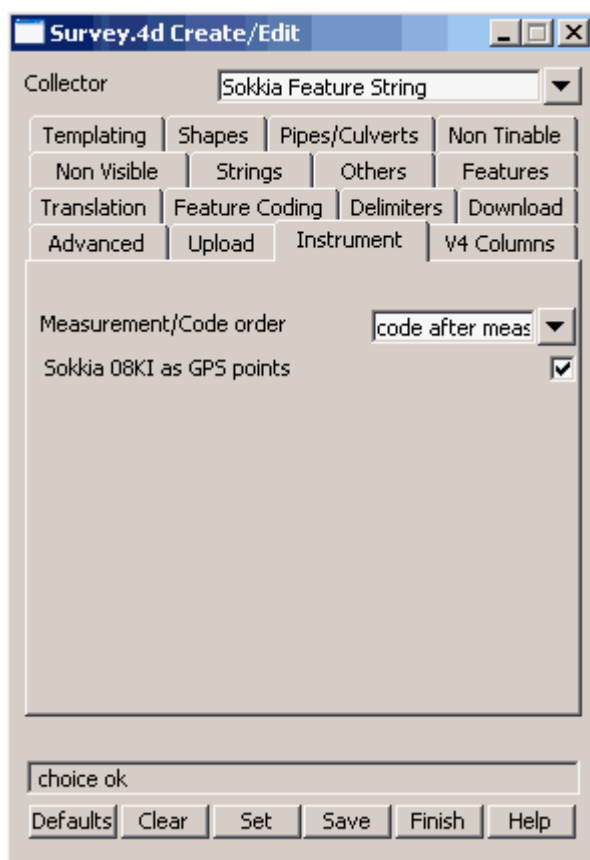

D 12D and Trimble GPS Controllers

The Trimble Geomatics Office software which comes with most Trimble GPS units can produce a Sokkia SDR file which is used by 12d Model as a raw data file.

However, the Trimble software writes out the (x,y,z) co-ordinates of GPS points as a "08KI" record which is normally treated by 12d Model as directly entered co-ordinates for a Station.

To overcome this problem, there is a flag in the data collector definitions to treat the Sokkia 08KI records as GPS points.

So before converting a Sokkia SDR file from a Trimble GPS unit, define a data collector which has a tick for the field *Sokkia 08KI as GPS points* on the *Instrument* tab of the **Survey.4d Create/Edit** panel.

This flag needs to be ticked on for reducing the SDR files created by Trimble GPS units

The code information that is entered on the Trimble in the field is appended the Sokkia 08KI record and is processed as blocks of information as given in the section "Field Coding for Non Leica Instruments" and the appendix "12D and Sokkia Instruments (SDR Files)" .

E 12D and Geodimeter Instruments

12d UDS's

The geodimeter allows the recording of information in a format specified by the user. Data for each label can be prompted for and measurements from the instrument can be registered. The user can assign a certain series of labels to a User Defined Sequence or UDS.

For 12d to reduce files from the geodimeter instruments, the recorded information from the instrument must be in a specific format that 12d can understand. A number of Geodimeter UDS files are supplied on the 12d Model Installation CD in the folder 'Other_Software\Geodimeter'.

For uploading or direct entry of UDS's to your particular instrument see you instrument manual.

*These UDS's have been set up so that 12d can convert the raw files from the instrument in a 12d field file. These UDS's should be installed **prior** to undertaking surveys that are to be reduced by 12d. The standard UDS that 12d supply is as follows:*

UDS 1 - used within UDS 8 to record 12d field op codes.

UDS 2 - prompts for additional data for a 12d field op code.

UDS 5 - job administration at the start of a job

UDS 6 - station co-ordinates entry

UDS 7 - station set up - name and instrument height

UDS 8 - data pick-up

UDS 5 is run at the beginning of the job and it runs UDS 6, which runs UDS 7 which runs UDS 8.

UDS 1 can be run as required from within UDS8 to give 12d field file op codes.

UDS 1 - used within UDS 8 to record 12d field op codes	UDS 5 - job admin at start of day	UDS 7 - station set up - name and instrument height	UDS 8 - data pick-up -----

12d standard UDS's for pick-up with Geodimeter

The Geodimeter data format is used as a raw data file by 12d Model and is converted into a 12d Field File before reduction by potentially 2 different macros:

- 1) geodat4d.4do (default) for use with the 12d standard UDS's.
- 2) geodat_qmrd.4do (Specialised reduction) for use with Queensland MRD UDS's.

For the geodat4d.4do macro (default) 12d Model uses the following Geodimeter labels:

0=	Information
1=	Attributes
2=	Station name or named point
3=	Instrument height
4=	Blocks
5=	Point number
6=	Target (signal) height
7=	Horizontal angle
8=	Vertical angle
9=	Slope distance
37=	Northing (X) value
38=	Easting (Y) value
39=	Height (Z) value
51=	Date
53=	Operator
90=	End of record, flush buffer
91=	12d Model field file op code
92=	Parameters for the previous 12d op code
95=	

In particular, the Geodimeter PCode label block (4=) is used as the text of blocks that are interpreted according to the descriptions given in the earlier section “Field Coding for Non Leica Instruments” .

A new conversion macro for V6.0, geodat_qmrd.4do recognises geodimeter Program 22 and Program 32 commands **if the following setup/procedures are used:**

1. The geodimeter should be set to record program numbers. This is shown by the label **0=Pn** in the raw file, where **n** is the program number and is assigned by the instrument. To set this up on the instrument use MENU 6 1(Switches) and turn Prg_Num on.
2. For 12d to convert raw files using geodimeter programs such as P22 and P32 the data must contain a label **61=n** each time an UDS or onboard program is started (Where **n** is the program number). This allows 12d to be able to determine when one program is finished and another started. Queensland MRD have created there own UDS's which utilise the **61=** label so that it is prompted for within the UDS's. They have also set up a UDS (UDS 6) which is used to place the label at the commencement of an onboard program such as program 22.

12d Field Ops Codes

In addition to the commands accessible from the blocks, most of the 12d field file op codes are accessible directly from the Geodimeter.

The label '91=' label is used to specify a 12d field file op code and any following '92=' labels provide any additional information required by the 12d op code.

The 12d field file ops codes apply to the measurement *before* the op code.

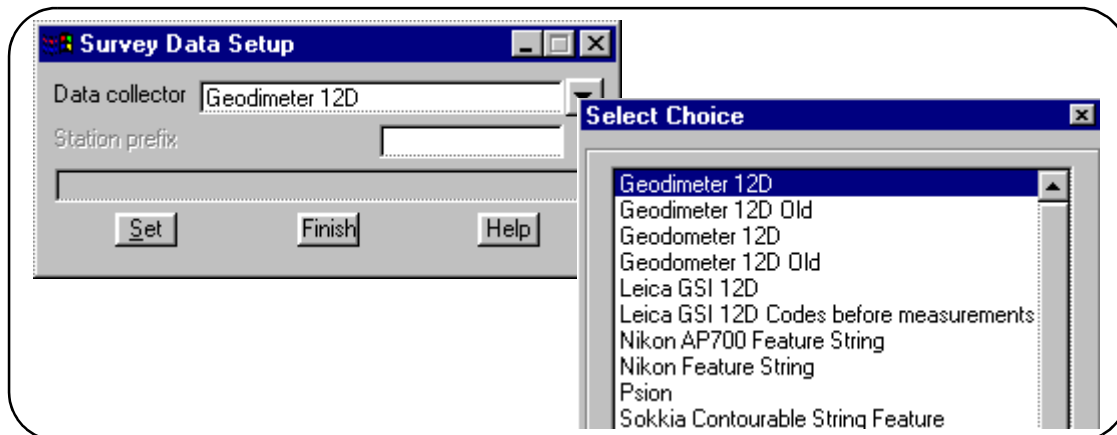

For a complete definition of the 12d Model field file and the 12d Model field file op codes, see the section “The 12d Field File Format”

Please continue to the next section “Example of Geodimeter File” .

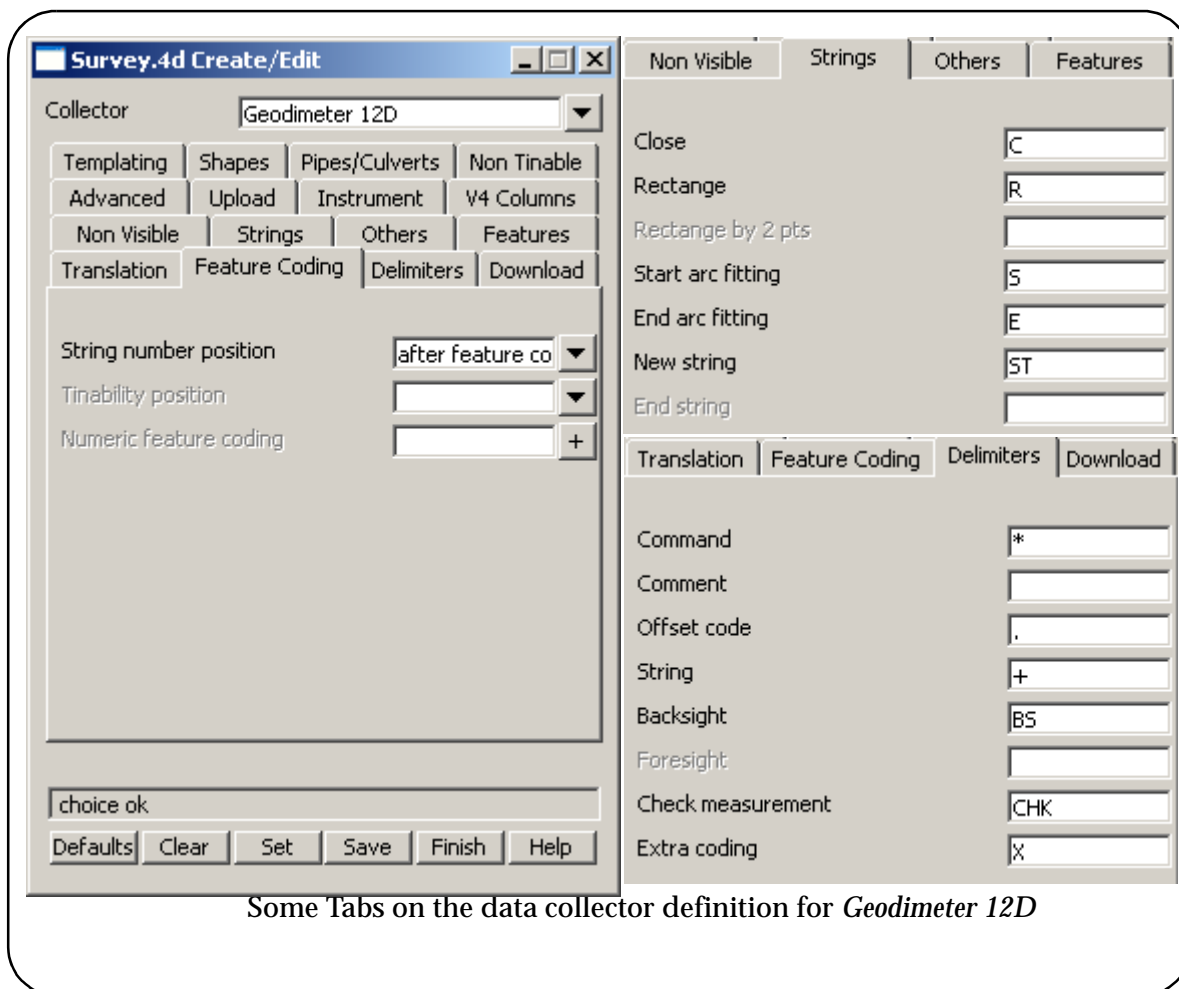

Example of Geodimeter File

The raw file 'Geodimeter.job' has been coded in accordance with the data collector definition *Geodimeter 12D* which is shipped with 12d Model. The 12d Model Geodimeter UDS's were used in the field pick-up.

The data collector *Geodimeter 12D* is set using the option *Survey=>Setup*

Some of the tabs on the *Geodimeter 12D* data collection definition as show below. Note that * is used as the Command (Block) delimiter, the *string number* is given after the *feature code*, S is used to start arc fitting and R is the Rectangle (make a parallelogram) command.

Some Tabs on the data collector definition for *Geodimeter 12D*

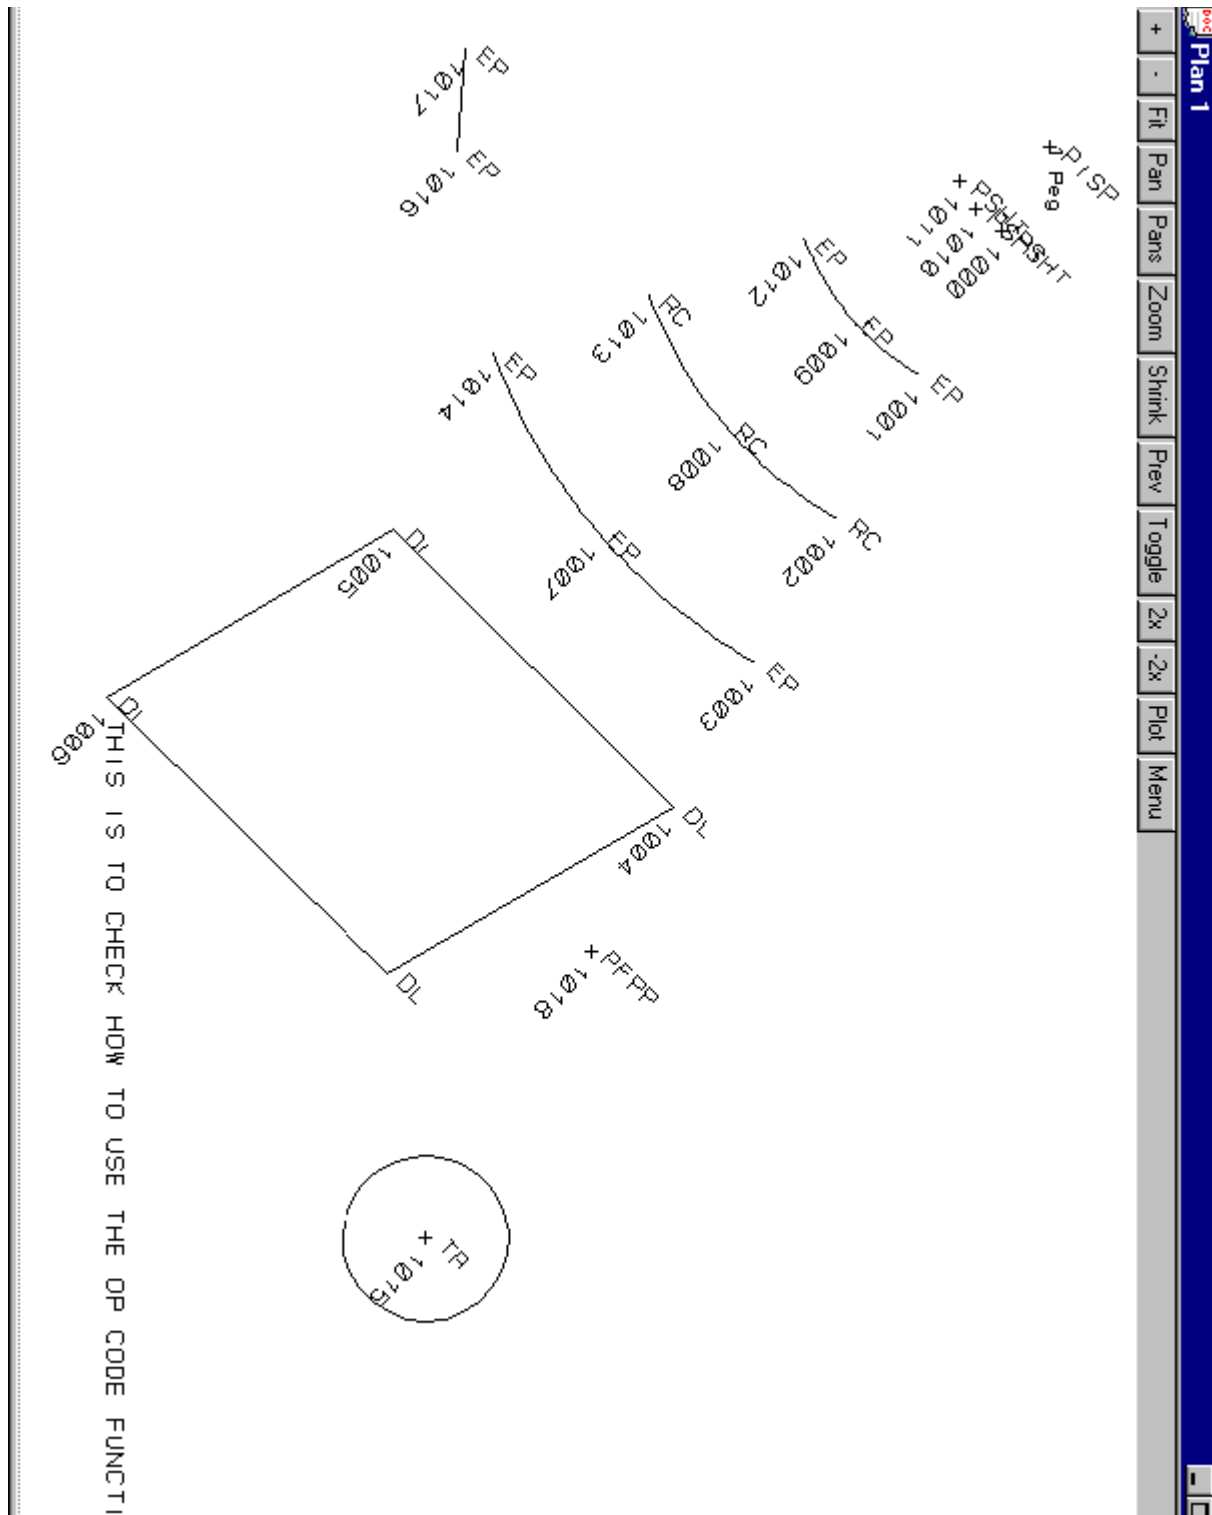

The listing of the raw file is now given, followed by a dump of a 12d Model view displaying the

job with string names (feature codes) and point numbers toggled on. The raw file 'Geodimeter.job' is in the Survey area of the training data. It can be converted into a 12d field file by using the default conversion macro geodat4d.4do.

Description	Geodimeter file	Description	Geodimeter file

**Plan View with of the Reduced Geodimeter Data Displayed
with Point Numbers and String Names (Feature Codes) Turned On**

The following raw field file has been taken from an QMRD Geodimeter 610 which has the QMRD UDS's installed. The file can be converted into a 12d field file by using the geodat_qmrd.4do. Note the inclusion of the activity codes (61=) that have been added to the file with the use of the UDS's. It also shows the use program 22 and the traverse extraction facility. For more information on traverse extraction see the section "Traverse coding" .

F 12D and Topcon Instruments

The Topcon data format is used as a raw data file by 12d Model and is converted into a 12d Field File before reduction.

G 12D and Leica TPS Instruments

The Leica GSI data format produced by the Leica TPS is used as a raw data file by 12d Model and is converted into a 12d Field File. The contents of the recorded data can be manipulated by use of the Leica's recording masks. The setup of which is explained in the section "Setup of Leica 1100 instrument for detail pickup and use with 12d" .

Each line (data block) of the Leica GSI file consists of between 1 and 12 words, with the words containing either 16 (8 characters for data) or 24 (16 characters for data) characters. The two formats will be referred to as the 8 format and 16 format respectively.

Measurement lines in the 8 format start with 11 and code lines start with 41.

For the 16 format, measurement lines start with *11 and code lines start with *41.

For an example of a GSI file in the 8 format, go to the section "Example of Leica GSI File" .

When using a Leica, the Leica screen can be standard or controlled by using a code.hex file on the 1000 series or a Geobasic program or Leica Codelist (.crf file) on the 1100 series.

4D Solutions provide a basic code.hex, Geobasic program and various Codelists(.crf files) on the 12d Model Installation CD in the folder 'Other_Software\Leica'. These can be customised to your requirements - please contact 4D Solutions for more information.

For an example of a Leica screen with standard set-up, Codelist and Geobasic program, please go to the section "Examples of Leica Screens" .

Please continue to the next section "Feature Codes and String Numbers" .

Feature Codes and String Numbers

The *feature code* and *string number* for a measurement are entered in the Leica by giving the *feature code* in the first word and the *string number* as the second word of a code line. The feature codes and string numbers can be alpha or numeric and up to 8 (16) characters long.

For example, the feature code ABC with string number 1 is recorded as:

410003+00000ABC 42....+00000001 for the 8 format

or

*410003+00000000000000ABC 42....+0000000000000001 for the 16 format.

Some surveyors like to define the *feature code* and *string number* **before** they make a measurement. Other surveyors prefer to define the *feature code* and *string number* **after** they make a measurement.

When defining a *Data Collector setup*, 12d Model allows the user to specify whether the feature code comes before or after a measurement:

code before measurement

The given *feature code* and *string number* applies to the **next** measurement and all subsequent measurements until another *feature code* and *string number* is entered.

code after measurement

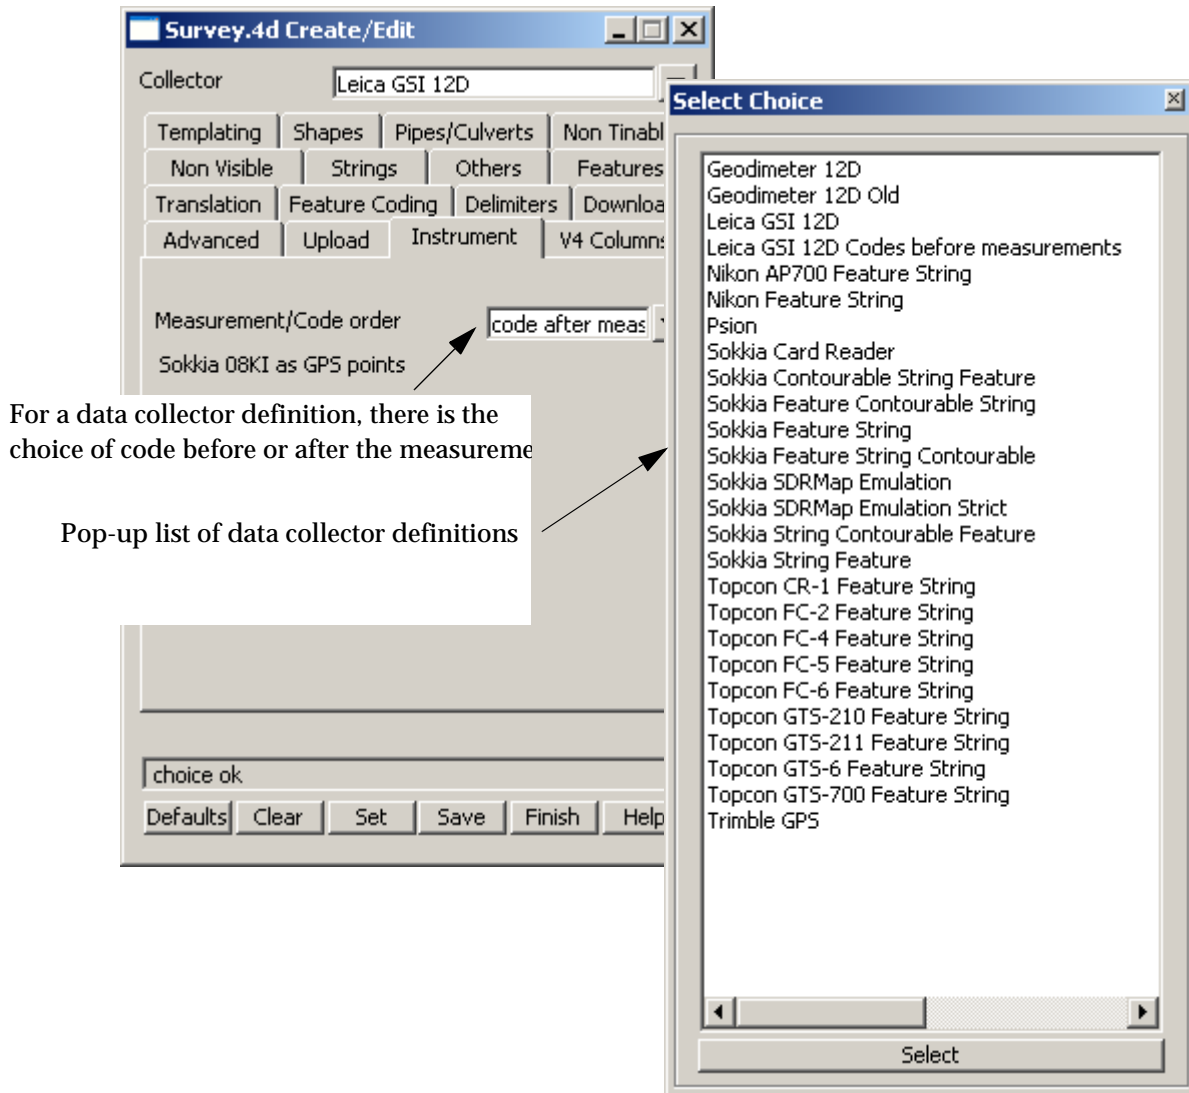

The given *feature code* and *string number* applies to the **last** measurement and all subsequent

measurements until another *feature code* and *string number* is entered.

However, for a particular data collector setup, it can be only be defined as one of the two choices. That is you can't change between having feature codes before or after measurements in the one raw file.

Summarising:

Whether feature code definitions come before or after the measurements is defined in the *Survey Data Collector* definition and is set by the *Measurement/Code order* field on the *Instrument* tab of the *Survey.4d Create/Edit* panel.

Please continue to the next section “Leica Field Codes” .

Leica Field Codes

12d Model also uses code lines to supply extra information using field codes.

All *field codes* are entered as the first word of the code line and to differentiate it from a *feature code*, the *field code* is preceded by a ".". Depending on the field code, more information may be required and it is entered in words 2 and above in the code line.

Each *field code* will now be described in detail.

For each *field code*, two lines and a paragraph of description are given:

- ▲ The first line consists of the *field code* and a short description of the purpose of the code.
- ▲ The second line gives the full syntax of the record for that *field code*.
- ▲ The paragraph gives a detailed description of the *field code*.

A **12d** Model code list containing **12d** Model field codes is available for the TPS to help coding in the field.

Field Code Conventions

In the syntax for the *field codes*, optional Words or groups of Words are enclosed in the square brackets [].

However, when the Leica TPS creates the Leica GSI format, the data in all Words is right justified and left filled with zeros. Consequently, **12d** Model strips leading zeros from all Words before processing the data.

This means that

- (a) an **optional Word** still exists in the file but its data field is simply **filled with zeros**.
- (b) any **text** in a Word **cannot start with a zero**. You would need to start with a space and then a zero.

In the *field code* descriptions, the point just measured is referred to as the **current measurement point**, the **current point** or the **last measurement point**.

The *string* that the current measurement point belongs to is called the **current string**.

For a summary of the Leica Field Codes, go to the section "Summary of Leica Field Codes"

For the full description of the Leica Field Codes, go to the section "Full Description of Leica Field Codes" .

For an example of a raw Leica file, please go to the section "Example of Leica GSI File" .

Full Description of Leica Field Codes

For a summary of the Leica Field Codes, go to the section “Summary of Leica Field Codes”

Field Code	Description of Record
------------	-----------------------

.2 Directly entered coordinates

Word 1 .2 Word 2 X Word 3 Y Word 4 Z Word 5 Feature_code

Word 6 String_number [Word 7 Point_number Word 8 Point_name]

A measurement point is created with the given feature code and string number and given (x, y, z) co-ordinates. No reduction is needed.

If a Point_name exists, then it is a **named measurement** and in the reduction, a 4d point string of name Point_name is created and mapped using the mapping file. The 4d text is the station prefix followed by Point_name. The Point_name is added to the internal list of named points for searching for co-ordinates.

Note that the Leica GSI format includes directly entered coordinates in a code line by data blocks with word indices 81, 82, 83 (Easting, Northing and Elevation).

.3 New instrument point - before the measurement

Word 1 .3 Word 2 Point_name Word 3 Instrument_height

Set up an instrument at the point with name Point_name. In the reduction, the (x, y, z) co-ordinates for Point_name are found by first searching the control model, then the list of previously named points in the reduction, point numbers of previous measurements and finally if Point_name is still not found, the user is asked to type in the (x, y, z) co-ordinates.

Note that the Leica GSI format includes setting up on a station in a measurement line by data blocks with word indices 84, 85, 86 (Station easting, Station northing and Station elevation) and 88 (Instrument height).

.4 Next measurement is a backsight - before the measurement

Word 1 .4 Word 2 Station_name [Word 3 Feature_code Word 4 String_number Word 5 Target_height]

The **next** measurement is to a backsight with name Station_name.

For traverse reduction, if the traverse code specified in the reduction panel matches the Feature code given in Word 3, the data will be included in a traverse reduction, string number can also be specified. Also the target height to the backsight can be given in the backsight command.

.5 New target height for subsequent measurements - before the measurement

Word 1 .5 Word 2 Target_height

Set a new target height to be used for all subsequent measurement points.

Note that the Leica GSI format can include the target height on each measurement line (word index 97).

.6 Next measurement is a Check measurement - before the measurement

Word 1 .6 Word 2 Station_name

The **next** measurement is a check measurement made to the station Station_name.

During reduction a two point super string (with name Station_name) from the instrument point to the measured point is created in the default model for the check measurement. The instrument point name, the station name and the differences between the measurement point co-ordinates and station co-ordinates are written as text along the super string. The differences between the measurement and the known point is also written to the report file.

.9 Scale factor for subsequent distances

Word 1 .9 Word 2 Scale_factor

Scale factor to apply to subsequent slope distances.

.11 Next measurement is to a named station - before the measurement

Word 1 .11 Word 2 Station_name [Word 3 Feature_code Word 4 String_number Word 5 Target_height]

This field code gives a name to a measurement so that it can be used in other field codes for setting up an instrument on, backsighting to or doing a check measurement to.

The *next* measurement locates a new instrument station with the name *Station_name*. A point with vertex text of *Station_name* is created. The *Station_name* is added to the internal list of named points for searching for co-ordinates.

If *Feature_code* exists, the point is given that *Feature_code*, otherwise the current feature code is used.

For traverse reduction, if the traverse code specified in the reduction panel matches the Feature code given in Word 3, the data will be included in a traverse reduction, string number can also be specified. Also the target height to the foresight can be given in this command.

.14 Feature code and string number - before or after measurement depends on the data collector definition

Word 1 .14 Word 2 Feature_code Word 3 String_number [Word 5 text Word 6 text] ...

A field code for entering the feature code and string number rather than using the standard method of using word 1 and word 2 This is for use with Leica quick codes which must put out a fixed first word. Any additional *text* is added to the end of any existing vertex text for the current measurement point. Any leading zeros in the text words will be ignored.

This field code is used *always before* or *always after* measurements depending on the *Measurement/code* field on the *Instrument* tab of the **Survey.4d Create/Edit** panel for the selected data collector definition.

.15 Vertical circle correction for subsequent measurements - before the measurement

Word 1 .15 Word 2 Vertical_circle_in_decimal_degrees

The *vertical_circle_in_decimal_degrees* is **subtracted** from the vertical circle value in any subsequent measurements.

.16 Additional code for point (multiply coded point) - after the measurement

Word 1 .16 Word 2 Feature_code Word 3 String_number [Word 4 Point_name] [Word 5 Point_text]

Additional coding for the current measurement point. A new measurement point is created at the same position as the current measurement point but with the *Feature_code* and *String_number* from this field code. The same point number is used as for the current measurement point.

If *Point_text* exists, it is used as the vertex text for that vertex of the super string.

If *Point_name* exists, then it is a **named measurement** and during reduction, a 4d point string of name *Point_name* is created and mapped using the mapping file. The 4d text is the station prefix followed by *Point_name*. The *Point_name* is added to the internal list of named points for searching for co-ordinates.

.17 Arc through previous three points - after the measurement of last point of arc

Word 1 .17 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 exists, then the current measurement point and the two previous points with the same feature code and string number as the current measurement point, are joined by an arc. If there is less

than three such points, no arc is fitted.

If the *Feature_code* and *String_number* exist, the last three previous three measurement points of the same *feature code* and *string number* are joined by an arc. If the current measurement point has that feature code and string number, then it is the third of the three points used. If there is less than three points, no arc is fitted.

If *Point_number* exists, then the *feature code* and *string number* are taken from the previous measurement point **with** that point number, and that point and the two measurement points previous to the pre-defined point of the same *feature code* and *string number*, are joined by an arc. If there is less than three points, no arc is fitted

See the Section “Arcs Through Points” for more information on arc fitting.

.18 Circle Feature - after the measurement

Word 1 .18 *Word 2* *Radius* [*Word 2* *Radius ...*]

Creates a feature string with the given radius and centred on the current measurement point. If there is more than one radius, then separate feature strings are created each with one of the radii.

.20 Close string - after the measurement

Word 1 .20 [*Word 2* *Feature_code* *Word 3* *String_number*] [*Word 4* *Point_number*]

If only *Word 1* exists, the current string is closed.

If the *Feature_code* and *String_number* exist, the last previous string with that *feature code* and *string number* is closed.

If *Point_number* exists, then the string containing that point number is closed.

See the Section “Close String” for more information on closing a string.

.21 Join last points of strings

Word 1 .21 *Word 2* *Feature_code* *Word 3* *String_number_1* *Word 4* *String_number_2*

In the final reduction, the last point of the string with the given *Feature_code* and *String_number_1* is joined to the last point of the string with given *Feature_code* and *String_number_2*. The created string has the given *Feature_code* (no string number is needed since it is the final phase of reduction when the string numbers are dropped).

See the Section “Joining Strings” for more information on joining strings.

.22 Join first to last point of strings

Word 1 .22 *Word 2* *Feature_code* *Word 3* *String_number_1* *Word 4* *String_number_2*

In the final reduction, the first point of the string with the given *Feature_code* and *String_number_1* is joined to the last point of the string with given *Feature_code* and *String_number_2*. The created string has the given *Feature_code* (no string number is needed since it is the final phase of reduction when the string numbers are dropped).

See the Section “Joining Strings” for more information on joining strings.

.23 Join first points of strings

Word 1 .23 *Word 2* *Feature_code* *Word 3* *String_number_1* *Word 4* *String_number_2*

In the final reduction, the first point of the string with the given *Feature_code* and *String_number_1* is joined to the first point of the string with given *Feature_code* and *String_number_2*. The created string has the given *Feature_code* (no string number is needed since it is the final reduction when the string numbers are then dropped).

See the Section “Joining Strings” for more information on joining strings.

.28 Text appended to a string name

Word 1 .28 *Word 2* *Text* [*Word 3* *Feature_code* *Word 4* *String_number*] [*Word 5* *Point_number*]

Text is appended to the string name. For example, if 1.200 is entered, “ 1.200” is appended to the string name.

If only *Text* is given, *Text* is appended to the string name of the current string.

If the *Feature_code* and *String_number* exist, then the last previous string with that *feature code* and *string number* has *Text* appended to the string name.

If *Point_number* exists, then the string containing that point number has *Text* appended to the string name.

.29 Note or memo - after the measurement

Word 1 .29 [*Word 2 text*] [*Word 3 text*]...

Any text may be entered and will be added to the check measurements model at the position of the current measurement point.

.30 Remove height from a point - that is make it a null height - after the measurement

Word 1 .30 [*Word 2 Feature_code* *Word 3 String_number*] [*Word 4 Point_number*]

If only *Word 1* exists, the height of the current measurement point is set to null.

If *Feature_code* and *String_number* exist, then the height of the last point of the previous string with that *feature code* and *string number* is set to null.

If *Point_number* exists, then the height of the point with that point number is set to null.

.37 Rectangle by two points

Word 1 .37 *Word 2 offset_in_metres* [*Word 3 Feature_code* *Word 4 String_number*] [*Word 5 Point_number*]

The rectangle is defined by two points (reference side) and a offset.

If a positive offset value is given, two points will be created to the right of the reference side.

If a negative offset value is given, two points will be created to the left of the reference side.

If *Feature_code* and *String_number* exist, the last two points with that *feature code* and *string number* are used and a fourth points are created to form a rectangle. The height of the two new points are set to null. The string is then closed.

If *Point_number* exists, then the *feature code* and *string number* of the point with that point number are used and processed as above. Note that the point with the point number is not necessarily used.

Two consecutive rectangles are unable to be defined side by side. In other words if the two points given are part of string of greater than two vertices, the command will only work for sets of two points that are exclusively defined. i.e. For a 5 point string, a rectangle can be defined by points 1 and 2, and 4 and 5.

See the Section “Rectangle” for more information.

.38 Make the previous segment non-tinable (not a breakline) - after the measurement

Word 1 .38 [*Word 2 Feature_code* *Word 3 String_number*] [*Word 4 Point_number*]

If only *Word 1* exists, the previous segment containing the current measurement point is set to non-tinable. That is, it will not be treated as a breakline in triangulations.

If the *Feature_code* and *String_number* exist, then the last segment of the previous string with that *feature code* and *string number* is set to non-tinable.

If *Point_number* exists, then the segment containing the point with that point number as an end point, is set to non-tinable.

.39 Make the next segment non-tinable (i.e. not a breakline) - after the measurement for the first point of the segment

Word 1 .39 [*Word 2 Feature_code* *Word 3 String_number*] [*Word 4 Point_number*]

If only Word 1 exists, the next segment containing the current measurement point as a starting point is set to non-tinable. That is, it will not be treated as a breakline in triangulations.

If the *Feature_code* and *String_number* exist, then the segment that is created in the future from the last point of the previous string with that *feature code* and *string number* is set to non-tinable.

If *Point_number* exists, then the segment containing the point with that point number as a start point, is set to non-tinable.

.40 Make a point non-tinable - after the measurement

Word 1 .40 [Word 2 *Feature_code* Word 3 *String_number*] [Word 4 *Point_number*]

If only Word 1 exists, the current measurement point is set to non-tinable. That is, it will not be included in triangulations.

If *Feature_code* and *String_number* exist, then the last point of the previous string with that *feature code* and *string number* is set to non-tinable.

If *Point_number* exists, then the point with that point number is set to non-tinable.

.41 Add additional text to the current measurement point - after the measurement

Word 1 .41 Word 2 *text* [Word 3 *text*] ...

The given *text* is added to the end of any existing vertex text for the current measurement point. Any leading zeros in the text words will be ignored.

.42 Add a radial offset - after the measurement

Word 1 .42 Word 2 *Radial_offset_in_metres* [Word 3 *Feature_code* Word 4 *String_number*] [Word 5 *Point_number*]

The *Radial_offset_in_metres* is used to adjust the position of the specified point by a plan distance from the specified points original position, along the plan line joining the current station to the specified point. A positive offset is away from the station, negative is toward the station.

If only Word 1 and 2 exist, the offset is used to adjust the position of the current measured point.

If *Feature_code* and *String_number* exist, then the last point of the previous string with that *feature code* and *string number* is adjusted.

If *Point_number* exists, then the point with that point number is adjusted.

See the Section “Offsets” for more information on offsets.

.43 Add a tangential offset - after the measurement

Word 1 .43 Word 2 *Tangential_offset_in_metres* [Word 3 *Feature_code* Word 4 *String_number*] [Word 5 *Point_number*]

The *Tangential_offset_in_metres* is used to adjust the position of the specified point by a plan distance from the specified points original position, at rights angles to the plan line joining the current station to the specified point. A negative offset is to the left (looking from the station), and positive is to the right (looking from the station).

If only Word 1 and 2 exist, the offset is used to adjust the position of the current measured point.

If *Feature_code* and *String_number* exist, then the last point of the previous string with that *feature code* and *string number* is adjusted.

If *Point_number* exists, then the point with that point number is adjusted.

See the Section “Offsets” for more information on offsets.

.44 Add a height offset - after the measurement

Word 1 .44 Word 2 *Height_offset_in_metres* [Word 3 *Feature_code* Word 4 *String_number*] [Word 5 *Point_number*]

If the height of the specified point is not null, then the *Height_offset_in_metres* adjusts the height of the point. A positive offset adds to the height, a negative offset reduces the height.

If only Word 1 and 2 *exist*, the offset is used to adjust the position of the current measured point.

If *Feature_code* and *String_number* exist, then the last point of the previous string with that *feature code* and *string number* is adjusted.

If *Point_number* exists, then the point with that point number is adjusted.

See the Section “Offsets” for more information on offsets.

.45 Make a parallelogram from the last three measurement points - after the measurement

Word 1 .45 [Word 2 *Feature_code* Word 3 *String_number*] [Word 4 *Point_number*]

If only Word 1 *exists*, the current measurement point and the two previous points from the current string are used and a fourth point is created to form a parallelogram (squashed rectangle) and the height of the fourth point is set to null. The string is then closed.

If *Feature_code* and *String_number* exist, the last three points with that *feature code* and *string number* are used and a fourth point is created to form a parallelogram (squashed rectangle) and the height of the fourth point is set to null. The string is then closed.

If *Point_number* exists, then the *feature code* and *string number* of the point with that point number are used and processed as above. Note that the point with the point number is not necessarily used.

See the Section “Rectangle” for more information on forming a parallelogram.

.46 Make the entire string a breakline or not (tinable or non-tinable)

Word 1 .46 [Word 2 *Breakline_type*] [Word 3 *Feature_code* Word 4 *String_number*]
[Word 5 *Point_number*]

Word 2: *Breakline_type*:

If *Breakline_type* is 0, the selected string is set to a point string and hence is not a breakline (non-tinable).

If *Breakline_type* is 1, the selected string is set to a *line* string and is therefore a breakline (tinable).

Words 3, 4, and 5:

If none of Words 3, 4 and 5 exist, the *Breakline_type* is applied to the current string.

If *Feature_code* and *String_number* exist, the *Breakline_type* is applied to the last string with that *feature code* and *string number*.

If *Point_number* exists, then the *Breakline_type* is applied to the string containing the point with that point number.

.47 Start a new string using the same feature code and string number - after the measurement of the first point of the new string

Word 1 .47 [Word 2 *Feature_code* Word 3 *String_number*] [Word 4 *Point_number*]

If only Word 1 *exists*, the current string is terminated (without including the current measurement point) and the current measurement point becomes the first point of a new string with the same feature code and string number.

If *Feature_code* and *String_number* exist, then the last point of the previous string with that feature code and string number becomes the first point of a new string with the same *feature code* and *string number*.

If *Point_number* exists, then the previous string containing the point with that point number is terminated *before* the point number point, and the point becomes the first point of a new string with the *same feature code* and *string number*.

.48 End a string

Word 1 .48 [Word 2 *Feature_code* Word 3 *String_number*] [Word 4 *Point_number*]

If only Word 1 *exists*, the current string is terminated (including the current measurement point).

If *Feature_code* and *String_number* exist, then the last point of the previous string with that feature

code and string number becomes the last point of that string.

If *Point_number* exists, then the previous string containing the point with that point number is terminated *after* the point number point

.50 Specify the bearing to correct for true north - used as the bearing datum difference

Word 1 .50 Word 2 *Bearing_in_decimal_degrees* [Word 3 *Text*]

The *Bearing_in_decimal_degrees* is used as the bearing datum difference for the current instrument set up. The *Text* and the *Bearing_in_decimal_degrees* are written to the reduction report file.

.51 Start using an existing field template - before the measurement

Word 1 .51 Word 2 [*Template_name*] [*mode*]

Start using the template *Template_name*. If *Template_name* is blank, the default template is used. If *mode* is "for", then the field template is used as a *forward* template.

"rev", then the field template is used as a *reverse* template.

"zig", then the field template is used as a *zig_zag* template and is used in the *forward* definition direction first.

"zag", then the field template is used as a *zig_zag* template and is used in the *reverse* direction first

If *mode* is blank, or 0, or anything other than "for", "rev", or "zag", then the field template is used as a *zig-zag* field template starting on a *zig*.

See the Section "Field Templates" for more information on field templates.

.52 Finish using a field template or finish recording a field template - after the measurement

Word 1 .52

Stops using the current field template or stops recording a field template.

.53 Pause using the current field template - after the measurement

Word 1 .53

Pause using the current field template or defining a field template, until a continue template (54) or a finish field template (52) code is given.

.54 Continue the current field template - before the measurement

Word 1 .54

Continue using the current field template or defining the current field template, which has been stopped by a *Pause* command (53). The *Continue* command only needs to be given once and applies to all *following* measurements until another *Pause* or *Finish* command is given.

.55 Start recording a field template - before the measurement

Word 1 .55 Word 2 [*Template_name*]

Start recording a field template with the name *Template_name*. If *Template_name* is non-blank, then the default field template is defined. The *feature_code* and *string_number* of the following measurements until a *Finish* code (52) are stored as the field template. There is no limit to the number of points in a field template.

See the Section "Field Templates" for more information on field templates.

.56 Skipping picking up points when using a field template - after the measurement of last point before skipping points

Word 1 .56 Word 2 [*num_skipped_points*]

Allows the user to skip picking up one or more points from the field template currently being used. The *next measurement* takes the *feature_code* and *string_number* from the next point of the field template definition. If *num_skipped_points* is missing, then only one point is skipped otherwise *num_skipped_points* are *skipped*.

.57 Delete points on a field template - after the measurement of last point

Word 1 .57 Word 2 [num_points_to_delete]

Allows the user to delete one or more points from the field template currently being used. The *next measurement* takes the *feature_code* and *string_number* from the next point of the field template definition.

.58 Insert points when using a field template - after the measurement of last point before inserting points

Word 1 .58 Word 2 *Feature_code* Word 3 *String_number* Word 4 *Multiple_code_flag* Word 5 *Insert_special_flag*

Allows the user to insert points into the field template currently being used. The *next measurement* takes the *feature_code* and *string_number* from the next point of the field template definition.

If the *Multiple_code_flag* = 1, then the feature code will be added to the previous defined template point else if *Multiple_code_flag* = 0 (default), it will be added to the template as a separate point.

If the insert is done at the end of a section and the *Insert_special_flag* = 1 the point will be added to the end of the current template section else it will be at the start of the next section.

.60 Start of arc through next three points - after the measurement of the first point of the arc

Word 1 .60 [Word 2 *Feature_code* Word 3 *String_number*] [Word 4 *Point_number*]

If only Word 1 *exists*, an arc is inserted through the current measurement point and the next two measured points with the same feature code and string number as the current measurement point. If there is less than three points, no arc is fitted.

If *Feature_code* and *String_number* exist, a search is made for a previously defined measurement with the same feature code or string number. An arc is inserted through the previous measurement and the next two measured points following this previous measurement with the same feature code and string number. If the current point has that feature code and string number, then it is the first of the three point. If there is less than three points, no arc is fitted.

If *Point_number* exists, then the *feature code* and *string number* are taken from the previous measurement point **with** that point number, and an arc is inserted through that point and the next two measurement points with the same *feature code* and *string number*. If there is less than three points, no arc is fitted

See the Section "Arcs Through Points" for more information on arc fitting.

.61 Start of arc through sets of three points until end of string, or a 62 occurs - after the measurement of the first point of the arc

Word 1 .61 [Word 2 *Feature_code* Word 3 *String_number*] [Word 4 *Point_number*]

The arcs are fitted as follows - the first arc is fitted through points one, two and three, the next arc through points three, four and five etc. If there is less than three points remaining at the end, then no arc is fitted to the end points.

If only Word 1 *exists*, arcs are inserted through the following sets of measurement points with the same feature code and string number as the current measurement point. The current measurement point is the *first* of the points.

If the current point has that feature code and string number, then it is the first of the points. If there is less than three points, then no arc is fitted.

If the *feature code* and *string number* exist, a search is made for a previously defined measurement with the same feature code or string number. An arc is inserted through the following measured points with the same feature code and string number as given in *point_description*. If the current point has that feature code and string number, then it is the first of the points.

If *Point_number* exists, then the *feature code* and *string number* are taken from the previous measurement point **with** that point number, and arcs are inserted through that point and the following measured points with the same *feature code* and *string number*.

If 12d Model encounters a *Start Arcs through sets of three points* but no *End Arcs* command for the string, then an *End Arcs* is assumed at the end of the string.

See the Section “Arcs Through Points” for more information on arc fitting.

.62 End the arcs begun by a 61 command - after the measurement of the last point of the arcs

Word 1 .62 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only *Word 1* exists, then the fitting of arcs through the points of the current string is stopped. The current measurement point is the *last* of the points used in the arc fitting.

If *Feature_code* and *String_number* exist, then the fitting of arcs through the points of the previous string with the same *feature code* and *string number* is stopped. If the current measurement point has that feature code and string number, then it is the last point used in the arc fitting.

If *Point_number* exists, then the point with that point number is the last point used in the arc fitting.

If 12d Model encounters an *End Arcs* (62) but no *Start Arcs through sets of three points* (61) command for the string, then an *Start Arcs through sets of three points* (61) is assumed to apply at the beginning of the string and hence arc fitting will be applied to the entire string.

See the section “Arcs Through Points” for more information on arc fitting.

There are field codes for adding user defined attributes to:

- (a) the current string being measured (i.e. the string containing the current measurement point)
 - (b) the current measurement point
 - (c) the next segment from the current measurement point (i.e. the segment joining the current measurement point and the *next* measured point of the same feature code and string number)
- or
- (d) the previous segment to the current measurement point (i.e. the segment joining the current measurement point to the previous measured point of the same feature code and string number).

The attributes can be named or unnamed and are coded in the following way:

If *Word 2* is missing (i.e. all zeros), then the attribute is an un-named attribute and the rest of the Words on the line is the attribute value. The attribute is given the special name "unnamed attribute n" for n=1, 2,

.68 Add an integer user defined attribute to the current string

Word 1 .68 [Word 2 Name] Word 3 Integer

Add an user defined integer attribute to the current string.

.69 Add a real user defined attribute to the current string

Word 1 .69 [Word 2 Name] Word 3 Real

Add a real (floating point) user defined attribute to the current string.

.70 Add text user defined attribute to the current string

Word 1 .70 [Word 2 Name] Word 3 Text [Word 4 Text] ...

Add a text user defined attribute to the current string.

.71 Add integer user defined attribute to the current point

Word 1 .71 [Word 2 Name] Word 3 Integer

Add an integer user defined attribute to the current measurement point.

.72 Add real user defined attribute to the current point

Word 1 .72 [Word 2 Name] Word 3 Real

Add a real (floating point) user defined attribute to the current measurement point.

.73 Add text user defined attribute to the current point

Word 1 .73 [Word 2 Name] Word 3 Text [Word 4 Text] ...

Add a text user defined attribute to the current measurement point.

.74 Add integer user defined attribute to the next segment

Word 1 .74 [Word 2 Name] Word 3 Integer

Add an integer user defined attribute to the next segment from the current measurement point.

.75 Add real user defined attribute to the next segment

Word 1 .75 [Word 2 Name] Word 3 Real

Add a real (floating point) user defined attribute to the next segment from the current measurement point.

.76 Add text user defined attribute to the next segment

Word 1 .76 [Word 2 Name] Word 3 Text [Word 4 Text] ...

Add a text user defined attribute to the next segment from the current measurement point.

.77 Add integer user defined attribute to the previous segment

Word 1 .77 [Word 2 Name] Word 3 Integer

Add an integer user defined attribute to the previous segment for the current measurement point.

.78 Add real user defined attribute for the previous segment

Word 1 .78 [Word 2 Name] Word 3 Real

Add a real (floating point) user defined attribute to the previous segment for the current measurement point.

.79 Add text user defined attribute to the previous segment

Word 1 .79 [Word 2 Name] Word 3 Text [Word 4 text] ...

Add a text user defined attribute to the previous segment for the current measurement point.

In addition, extra codes allow **12d** Model pipe strings to be coded in the field.

.80 Pipe invert point (bottom of the pipe) - after the measurement

Word 1 .80 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 *exists*, the current measurement point is on the invert (bottom) of a pipe. This is the default for measurements to points on pipe strings. If the point is not part of a pipe string, it is ignored.

If *Feature_code* and *String_number* exist, the last point of the previous string with the same *feature code* and *string number* is on the invert (bottom) of a pipe. If the point is not part of a pipe string, it is ignored.

If *Point_number* exists, then the point with that point number is on the invert (bottom) of a pipe. If the point is not part of a pipe string, it is ignored.

.81 Pipe axial point (centre of the pipe) - after the measurement

Word 1 .81 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only *Word 1* exists, the current measurement point is on the axis (centre) of a pipe. If the point is not part of a pipe string, it is ignored.

If *Feature_code* and *String_number* exist, the last point of the previous string with the same *feature code* and *string number* is on the axis (centre) of a pipe. If the point is not part of a pipe string, it is ignored.

If *Point_number* exists, then the point with that point number is on the axis (centre) of a pipe. If the point is not part of a pipe string, it is ignored.

.82 Pipe obvert point (top of the pipe) - after the measurement

Word 1 .82 [*Word 2 Feature_code Word 3 String_number*] [*Word 4 Point_number*]

If only *Word 1* exists, the current measurement point is on the obvert (top) of a pipe. If the point is not part of a pipe string, it is ignored.

If *Feature_code* and *String_number* exist, the last point of the previous string with the same *feature code* and *string number* is on the obvert (top) of a pipe. If the point is not part of a pipe string, it is ignored.

If *Point_number* exists, then the point with that point number is on the obvert (top) of a pipe. If the point is not part of a pipe string, it is ignored.

.83 Start recording a shape - before the measurement

Word 1 .83 [*Word 2 Shape_name*]

Start recording a shape with the name *Shape_name*. If *Shape_name* is non-blank, then the default field Shape is defined by the *feature_code* and *string_number* of the following measurements until a *Finish* code (84) are stored as the shape. There is no limit to the number of points in a shape.

See the Section "Field Templates" for more information on field templates.

.84 Finish using a shape definition or finish recording a shape - after the measurement

Word 1 .84

Stops using the current shape or stops recording a shape.

.85 Shape parallel

Word 1 .85 *Word 2 Shape_name* [*Word 3 Feature_code Word 4 String_number*] [*Word 5 Point_number*]

If *Feature_code* and *String_number* exist, the last string with the same *feature code* and *string number* has the shape applied to the entire length of the string.

If *Point_number* exists, then the string containing that point number has the shape applied to the entire length of the string.

Parallelling the shape will produce separate strings for each point of the shape.

.86 Shape extrude

Word 1 .86

Word 1 .85 *Word 2 Shape_name* [*Word 3 Feature_code Word 4 String_number*] [*Word 5 Point_number*]

If *Feature_code* and *String_number* exist, the last string with the same *feature code* and *string number* has the shape applied to the entire length of the string.

If *Point_number* exists, then the string containing that point number has the shape applied to the entire length of the string.

Extruding the shape will produce a single string for the shape.

.92 Remove all z-values for a string (i.e. make all z-values null) - after the measurement

Word 1 .92 [Word 2 Point_line_type] [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

If only Word 1 exists, all z-values for the current string are removed.

If *Feature_code* and *String_number* exist, the last string with the same *feature code* and *string number* has all its z-values removed.

If *Point_number* exists, then the string containing that point number has all its z-values removed.

If *Point_line_type* is 0, the selected string is set to a point string.

If *Point_line_type* is 1, the selected string is set to a *line* string.

.93 Set the Point-line type - after the measurement

Word 1 .93 [Word 2 Point_line_type] [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

If only Word 1 exists, the current string is created as a point string.

If *Feature_code* and *String_number* exist, the last previous string with the same *feature code* and *string number* has its point-line type modified.

If the *point number* exists, then the string containing that point number has its point-line type modified.

If *Point_line_type* is 0, the selected string is set to a point string.

If *Point_line_type* is 1, the selected string is set to a *line* string.

.94 Use name library/mapping file for vertex text on the string - name mapping - after the measurement

Word 1 .94 [Word 2 Point_line_type] [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

If this field code exists then during reduction, vertex text is creating using either the name library, or if the name library doesn't exist, the map file. If neither exist then the field code is ignored.

if a name library is used and the feature code of the string is found in the first column of the name library, then the entry from the second column of that row will be used as text for *all* vertices of the string that don't already have vertex text. As a default, the string is set as a point string.

if the map file is used and the feature code of the string is found in the first column of the map file, then the *string name* field of the map file is used as vertex text for all vertices that don't already have text. As a default, the string is set as a point string.

If only Word 1 exists, then name mapping is applied to the current string.

If *Feature_code* and *String_number* exist, then name mapping is applied to the last previous string with the same *feature code* and *string number*.

If *Point_number* exists, then name mapping is applied to the string containing that point number.

If *Point_line_type* is 0, the selected string is set to a point string.

If *Point_line_type* is 1, the selected string is set to a *line* string.

.95 Circular Pipe string - after the measurement

Word 1 .95 Word 2 Diameter [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

Pipe strings are always line strings and are stored with the justification of the majority of the string points. Individual pipe points are picked up either top (obvert), centre (axial) or bottom (invert) of the pipe using field codes 80, 81 and 82.

If only Word 1 and 2 exists, the current string is created as a pipe string with the given diameter.

If *Feature_code* and *String_number* exist, the last string with the same *feature code* and *string number* is created as a pipe with the given diameter.

If *Point_number* exists, then the string containing that point number is created as a pipe string with the given diameter.

.96 Box Culvert string - after the measurement

Word 1 .95 Word 2 Width Word 3 Height [Word 4 Feature_code Word 5 String_number] [Word 6 Point_number]

Culvert strings are always line strings and are stored with the justification of the majority of the string points. Individual culvert points are picked up either top (obvert), centre (axial) or bottom (invert) of the culvert using field codes 80, 81 and 82.

If only *Word 1, 2 and 3 exists*, the current string is created as a culvert string with the given width and height.

If *Feature_code* and *String_number* exist, the last string with the same *feature code* and *string number* is created as a culvert with the given width and height.

If *Point_number* exists, then the string containing that point number is created as a culvert string with the given width and height.

.99 Terminate processing

Word 1 .99

Stop processing the field file at this line. Useful for debugging errors.

.107 Make the previous segment invisible - after the measurement

Word 1 .107 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only *Word 1* exists, the previous segment containing the current measurement point is set to invisible.

If the *Feature_code* and *String_number* exist, then the last segment of the previous string with that *feature code* and *string number* is set to invisible.

If *Point_number* exists, then the segment containing the point with that point number as an end point, is set to invisible.

**.108 Make the next segment invisible - after the measurement for the first
point of the segment**

Word 1 .108 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only *Word 1* exists, the next segment containing the current measurement point as a starting point is set to invisible.

If the *Feature_code* and *String_number* exist, then the segment that is created in the future from the last point of the previous string with that *feature code* and *string number* is set to invisible.

If *Point_number* exists, then the segment containing the point with that point number as a start point, is set to invisible.

.109 Make a point invisible - after the measurement

Word 1 .109 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only *Word 1* exists, the current measurement point is set to invisible.

If *Feature_code* and *String_number* exist, then the last point of the previous string with that *feature code* and *string number* is set to invisible.

If *Point_number* exists, then the point with that point number is set to invisible.

.110 Start buildings face observations - before the measurements

Word 1 .110 Word 2 [Building_name]

Start recording a field template with the name *Building_name*. If *Building_name* is non-blank, then the default building face is defined. The *feature_code* and *string_number* of the following measurements until a *Finish* code (111) are stored as the building face. There is no limit to the number of points in a

building face.

.111 End building face observations

Word 1 .111 *Word 2* [*Building_name*]

If only Word 1 *exists*, the current building face observation set is finished (including the current measurement point).

Notes

1. Arc fitting is applied *after* the Joins are processed. Hence the new joined strings are created and then curve fitting is applied according to the arc codes (start arc, end arc, fit arcs, stop fitting arcs etc.) on any vertex of the string.

For a summary of the Leica Field Codes, go to the section “Summary of Leica Field Codes”

Summary of Leica Field Codes

Most of the field codes are entered after the measurement is taken and they will have a (AM) after the description. Some of the field codes are entered before the measurement is taken (mainly set up codes) and will have a (BM) after the description.

Field Code	Description of Record
.2	Directly entered coordinate measurement
.3	New instrument setup point (BM)
.4	Measurement to backsight (BM)
.5	New target height (BM)
.6	Check measurement (BM)
.9	Scale factor for subsequent distances (BM)
.10	Three hair stadia measurement
.11	Measurement to a named station (BM)
.15	Vertical circle correction (BM)
.14	A field code for entering Feature code and String number - BM or AM depends on data collector definition
.16	Multiply coded point (AM)
.17	Arc through previous three points (AM of last point of arc)
.18	Circle Feature (AM)
.20	Close string (AM)
.21	Join last points of strings
.22	Join first to last point of strings
.23	Join first points of strings
.28	Add text to the string name (AM)
.29	Note or memo (AM)
.30	Remove height from a point - that is make it a null height (AM)
.37	Rectangle by two points
.38	Make the previous segment non-tinable (AM of end point of segment)
.39	Make the next segment non-tinable (AM of first point of segment)
.40	Make a point non-tinable (AM)
.41	Add additional text (AM)
.42	Add a radial offset (AM)
.43	Add a tangential offset (AM)
.44	Add a height offset (AM)
.45	Make a parallelogram from the last three measurement points (AM)
.46	Make the string a breakline or not
.47	Start a new string using the same feature code and string number (AM of first point of new string).
.48	End a string -
.50	Specify the bearing to correct for true north - used as the bearing datum difference
.51	Start using an existing field template (BM)
.52	Finish using a field template or finish recording a field template (AM)
.53	Pause the current field template until a continue op code (54) or a finish template (52)
.54	Continue the current field template (BM)
.55	Start recording a field template (BM)
.56	Skip picking up one or more points from a field template (AM of last point before skipping)
.57	Delete one or more points from a field template (AM)
.58	Insert a point into a field template (BM)
.60	Arc through next three points (AM of first point of arc)
.61	Start of arc through sets of three points until end of string, or a 62 occurs (AM of first point of arc)
.62	End the arcs begun by a 61 command (AM of last point of arcs)
.68	Add an integer user defined attribute to the current string (AM of any point of the string)
.69	Add a real user defined attribute to the current string (AM of any point of the string)
.70	Add text user defined attribute to the current string (AM of any point of the string)
.71	Add integer user defined attribute to the current point (AM)

- .72 Add real user defined attribute to the current point (AM)
- .73 Add text user defined attribute to the current point (AM)
- .74 Add integer user defined attribute to the next segment (AM of first point of the segment)
- .75 Add real user defined attribute to the next segment (AM of first point of the segment)
- .76 Add text user defined attribute to the next segment (AM of first point of the segment)
- .77 Add integer user defined attribute to the previous segment (AM of last point of the segment)
- .78 Add real user defined attribute for the previous segment (AM of last point of the segment)
- .79 Add text user defined attribute to the previous segment (AM of last point of the segment)
- .80 Pipe invert point (bottom of the pipe) (AM)
- .81 Pipe axial point (centre of the pipe) (AM)
- .82 Pipe obvert point (top of the pipe) (AM)
- .83 Start recording a shape - before the measurement
- .84 Finish using a shape definition or finish recording a shape - after the measurement
- .85 Shape parallel
- .86 Shape extrude
- .92 Remove all z-values for a string (i.e. make all z-values null) (AM of point of the string)
- .93 Set the Point-line type
- .94 Use name library file/ mapping file for vertex text on the string - name mapping
- .95 Circular pipe string with diameter (AM)
- .96 Box culvert string with dimensions (AM)
- .99 Terminate processing
- .107 Make the previous segment invisible - after the measurement
- .108 Make the next segment invisible - after the measurement for the first
point of the segment
- .109 Make a point invisible - after the measurement
- .110 Start buildings face observations - before the measurements
- .111 End building face observations

For a full description of the Leica codes, please go to the section "Full Description of Leica Field Codes" .

For an example of a raw Leica file, please go to the section "Example of Leica GSI File" .

Examples of Leica Screens

Standard Screen

When using a Leica instrument with no code.hex on the 1000 series, or Geobasic program or Codelist (.crf file) on the 1100 series, hitting the *Code* button brings up the standard Leica screen:

The information entered in *Code* goes to Word 1 of the line written to the Leica GSI file.

The information in *Info 1* to *Info 8* go to Word 2 to Word 9 respectively of the line written to the GSI file.

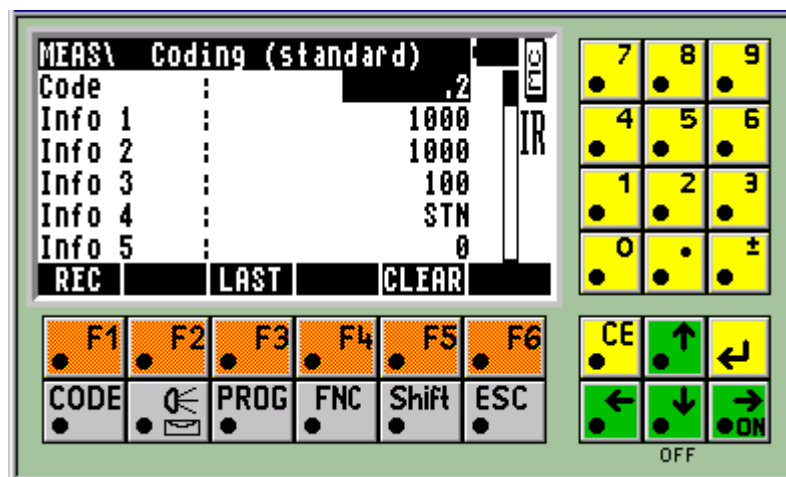

As an example, to enter a *directly entered co-ordinate* (the 2 field code),

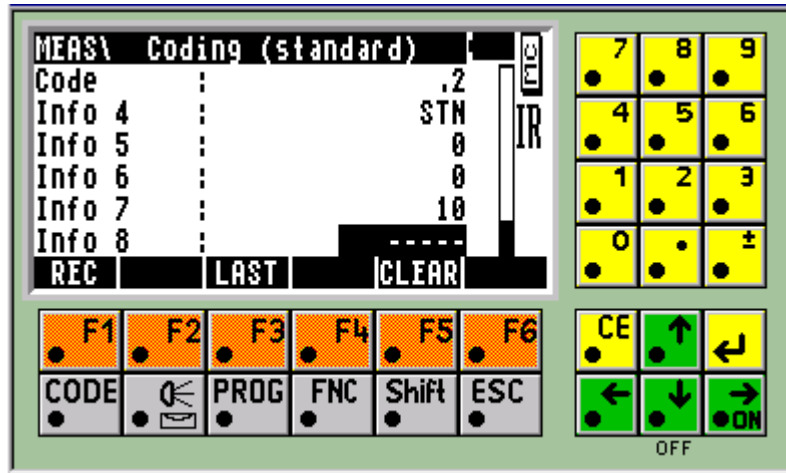

"2" is entered in the *Code* field

X, Y and Z in *Info 1*, *Info 2* and *Info 3* respectively.

the feature code (STN) is entered into *Info 4*

the station name "10" is entered into *Info 7*

To enter a *feature code and string number* to be used for measurements
the feature code is entered into the *Code* field
the string number is entered into *Info 1*.

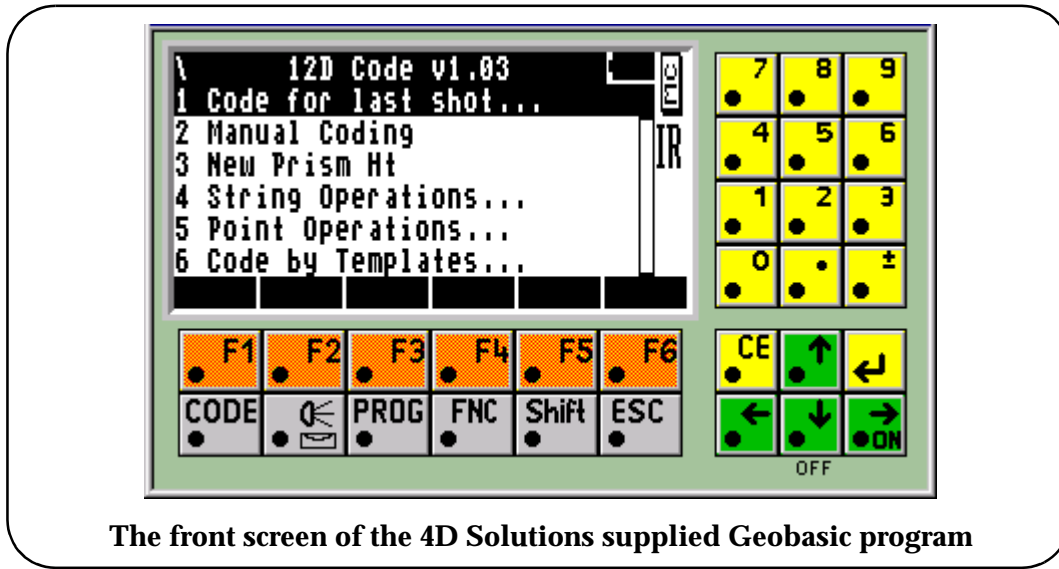

Leica Geobasic Program

A Leica Geobasic program gives the programmer full control over the Leica screen.

WARNING

Only one Geobasic program can exist on the Leica at any one time. Loading a Geobasic program will over write the existing Geobasic program on the instrument. Make sure you have a backup copy of the existing Geobasic program on your computer before loading a new one onto the instrument.

If you do not have a backup copy of the existing Geobasic program, do not load a new one.

The front screen of the 4D Solutions supplied Geobasic program

Leica Codelist

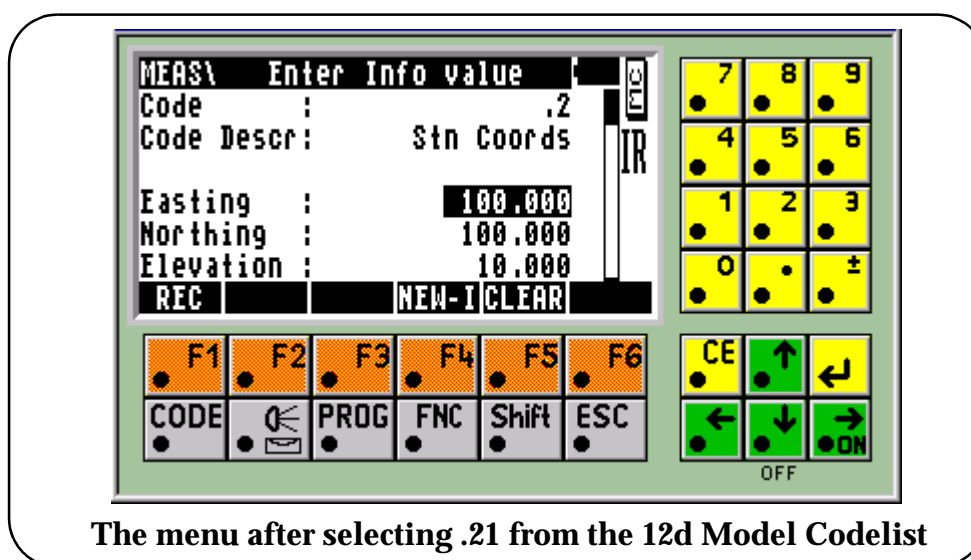

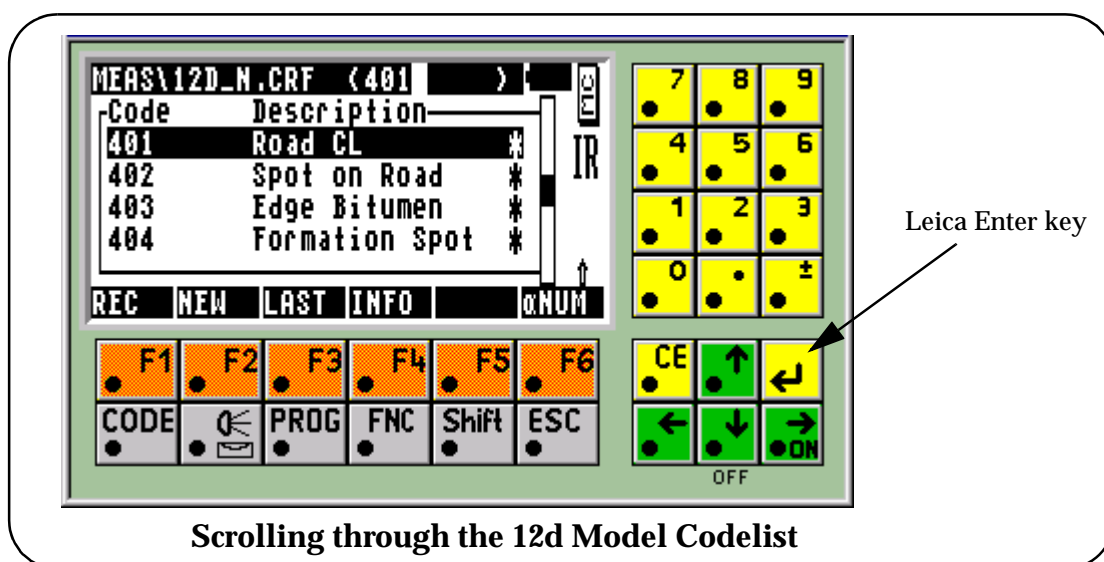

A Leica Codelist (.crf file) controls what is displayed and validated on the Leica screen and what values are recorded whenever the *Code* button is selected. For example, when using the 4D Solutions supplied Codelists, a list of defined feature codes and descriptions are displayed.

The Codelist controls what codes are displayed and whenever a code is selected, what information is required for that code. The Codelist also specifies what information is written out to the GSI file for that code.

After hitting the *Code* button, the list of codes from the Codelist is displayed in alphanumeric order. Because the 12d Model field codes start with a ".", they will appear at the top of the list.

A code can be typed in or the list can be scrolled through using the arrow keys.

The highlighted code is selected by pressing the Leica Enter Key. The menu for the selected code then appears. The line of data is written out to the GSI file when the F1 (REC) button is selected.

Setup of Leica 1100 instrument for detail pickup and use with 12d

The following relates to the setup of a Leica 1100 series instrument for topographic/detail pickup and use with 12d.

Setting up the Instrument

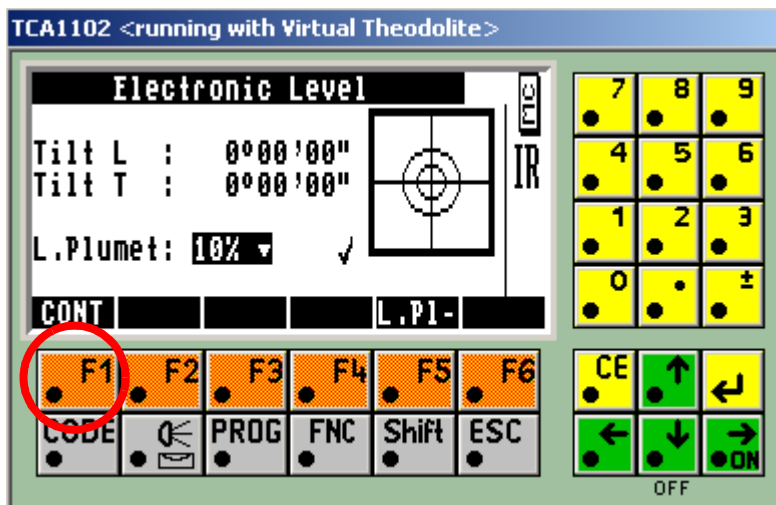

Copying the CRF file

A number of example .crf files are include on the installation CD. These can be found in the directory Other_Software\Leica\ . For the purpose of this documentation, we will use the file 12D_DS.CRF which is designed for detail pickup. This file should be copied from the 12d CD to the folder "Code" on the Leica card.

This file contains all of the field codes used in 12d model along with a sample code listing

Set up the display and record masks

Turn on and level instrument

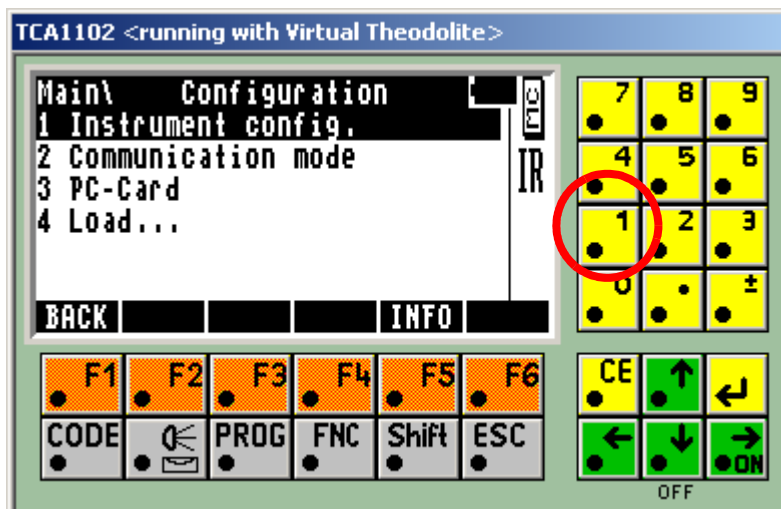

Press F1 to Continue

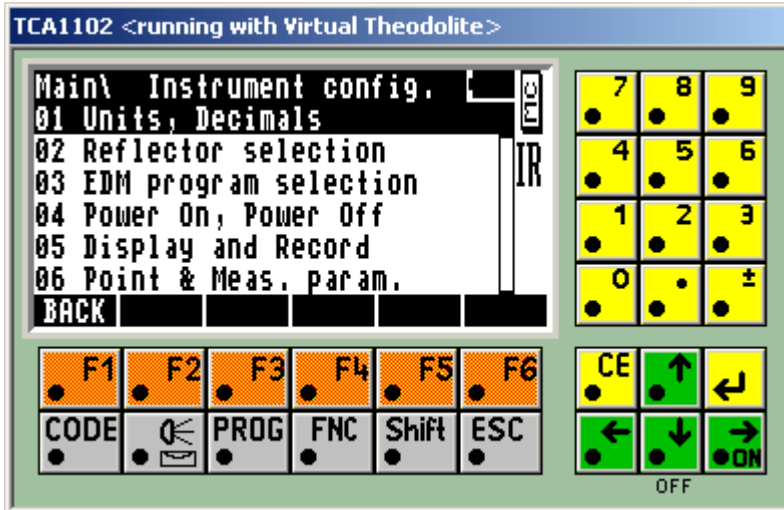

Press 5 to configure the instrument

Press 1 for instrument configuration

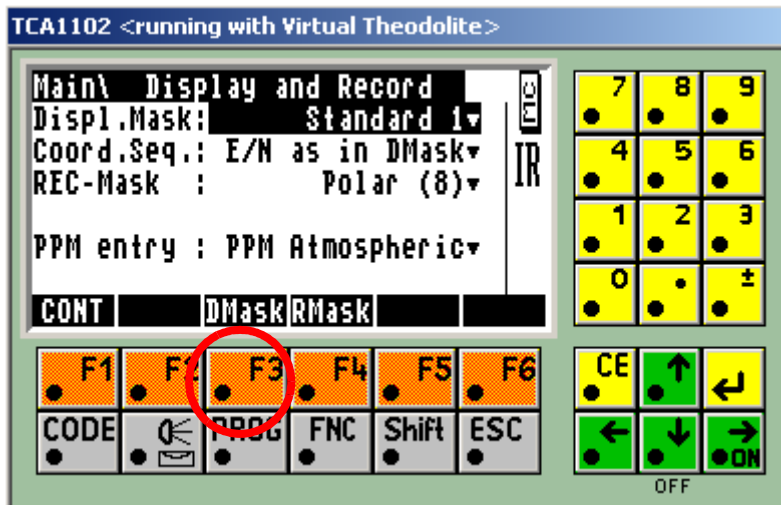

Press 05 for Display and Record mask setup

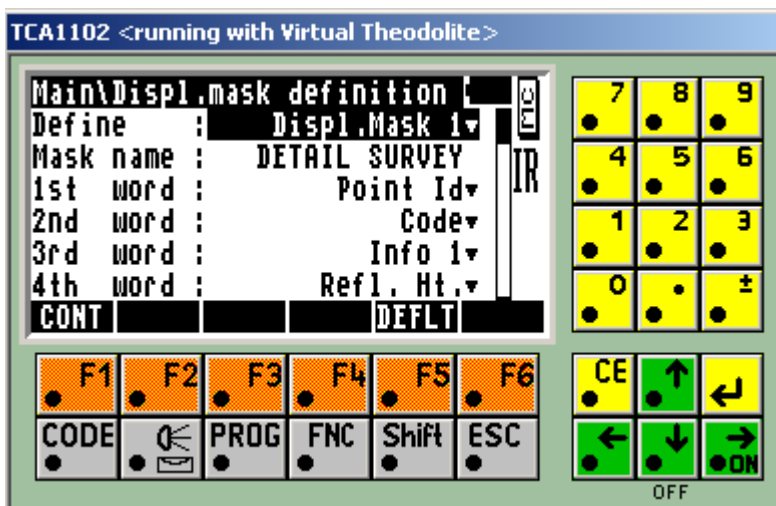

Display mask:

Press F3 to set up display mask

Type in the description **DETAIL SURVEY** for the Mask name

Select the following settings:

1st Word.....Point Id

2nd Word.....Code

3rd Word.....Info 1

4th Word.....Refl. Ht.

5th Word.....Hz

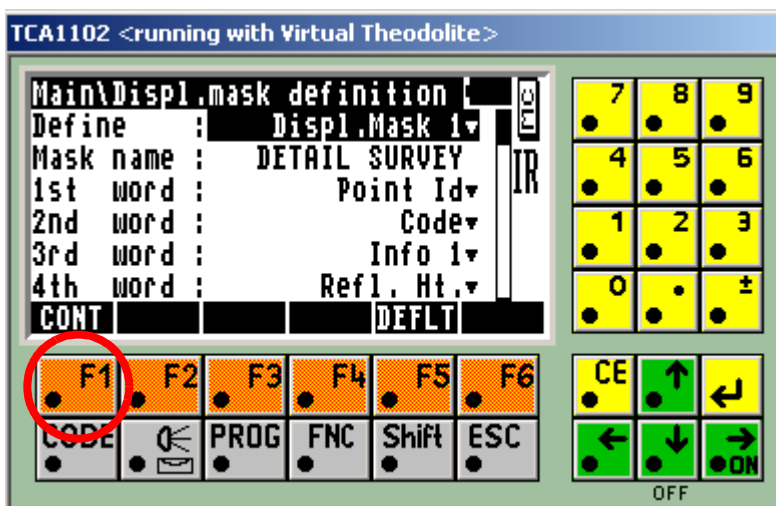

6th Word.....Horiz. Dist

7th Word.....East

8th Word.....North

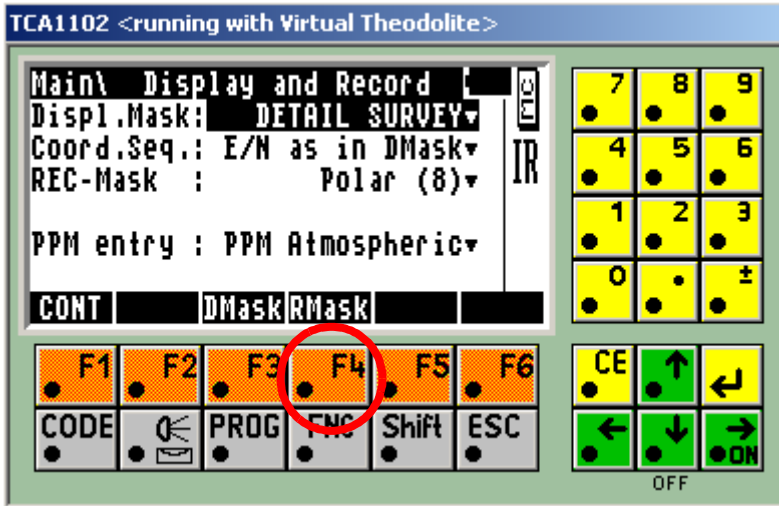

9th Word.....Elev

Press F1

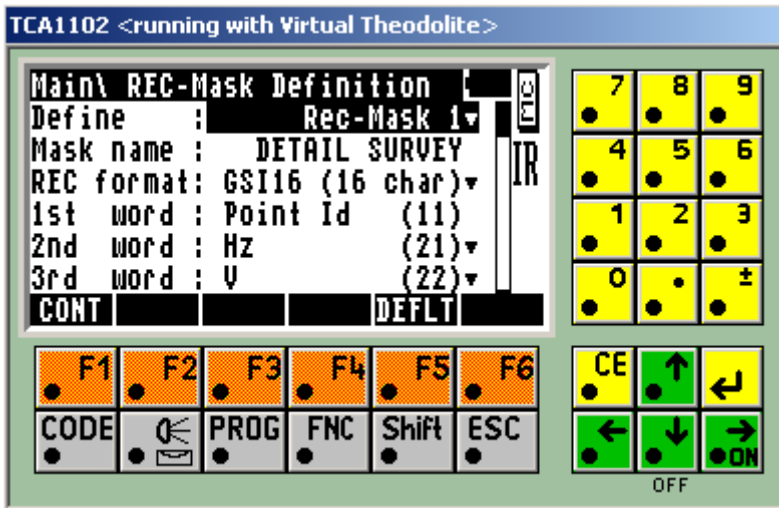

Record mask:

Press F4 to set up record mask

Type in the description DETAIL SURVEY for the Mask name

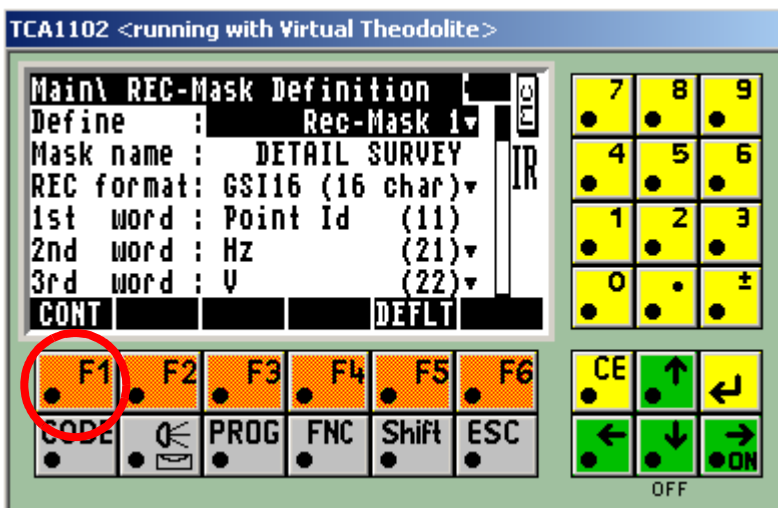

Select the following settings:

- REC format....GSI16 (16 char)
- 1st Word.....Point Id (11)
- 2nd Word.....Hz (21)
- 3rd Word.....V (22)
- 4th Word.....Slope Dist (31)
- 5th Word.....Ref. Ht. (87)
- 6th Word.....East (81)
- 7th Word.....North (82)

8th Word.....Elev (83)

Press F1 to exit menu

Leica field codes

It is important to know when the code is entered into the instrument as some codes should precede a reading (BM) and some come after (AM). In this manual if a code is related to the current string then it is placed before the reading.

Below is a list of the commonly used codes to be used

- .2 Directly entered coordinates
- .3 New instrument station
- .4 Backsight reading (BM)
- .5 Height of target (BM)
- .6 Check measurement (BM)

.9	Scale factor (BM)
.11	Foresight station (BM)
.14	Feature code and string number (Use for Leica quick codes only)
.15	Vertical circle correction (d.dddd) (BM)
.16	Additional code for point (AM)
.17	Arc thru last 3 points (AM)
.18	Circle (AM)
.20	Close string (AM)
.29	Note (AM)
.30	Remove height from point (AM)
.37	Rectangle by two points (AM)
.38	Make last segment non tinable (AM)
.39	Make next segment non tinable (AM)
.40	Make point non tinable (AM)
.42	Add radial offset (AM)
.43	Add tangential offset (AM)
.44	Add height offset (AM)
.45	Create parallelogram from last three points (AM)
.47	Start new string with same code and string no. as previous string (AM)
.48	End string (AM)....Not generally used

Templates

.51	Start template readings (BM)
.52	Finish template readings (AM)
.53	Pause template (AM)
.54	Continue a template (BM)
.55	Start recording template (BM)
.56	Skip points on template (BM)

Arcs

.60	Arc thru next 3 points (AM).....See also .17
.61	Arc through sets of 3 points until .62 code entered (BM)
.62	End of arc from .61 (AM)

Pipes

.80	Reading taken to invert level of pipe (AM)
.81	Reading taken to centre of pipe (AM)
.82	Reading taken to obvert level of pipe (AM)
.95	Circular pipe diameter (AM)
.96	Box culvert dimensions (AM)

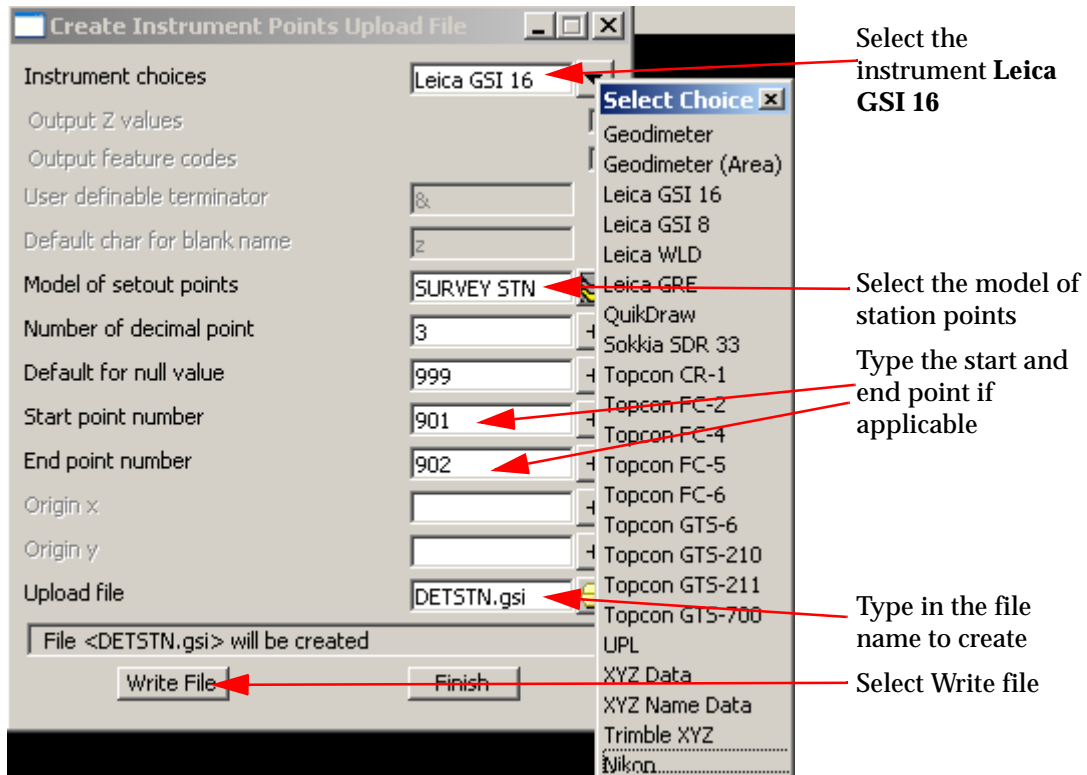

- .92 Remove heights from string (AM)
- .107 Make previous segment invisible (AM)
- .108 Make next segment invisible (AM)

Setting up files

The existing station coordinates for a pickup can be entered into the Leica by hand or they can be uploaded using 12d. The 12d upload sequence will be described here.

Uploading coordinate file

Select option **Survey=>Upload=>Create points upload file**

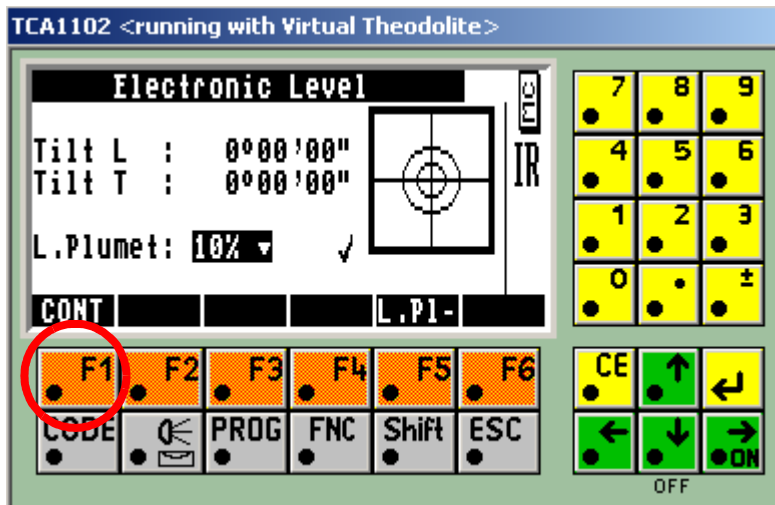

Copy the upload file

The file upload file should be copied to the folder "GSI" on the Leica card

Data file setup

Turn on and level instrument

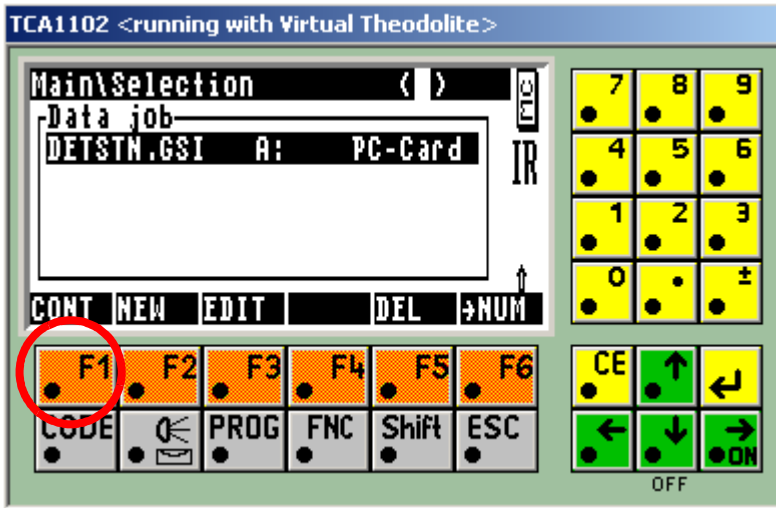

Press F1 to Continue

Press 2 to select Data job file.

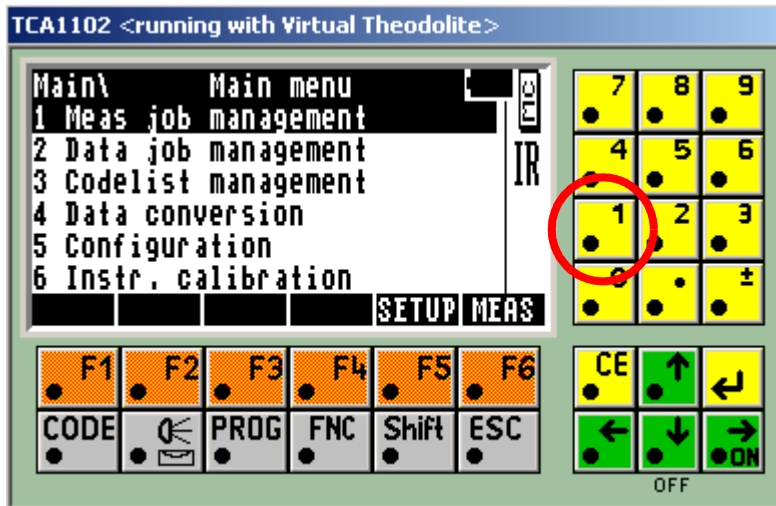

This is the file containing the control points if uploaded or if entered during the survey. Keep the file name separate from the measured data file name

Select the file to use followed by the F1 key or press F2 to create a new file

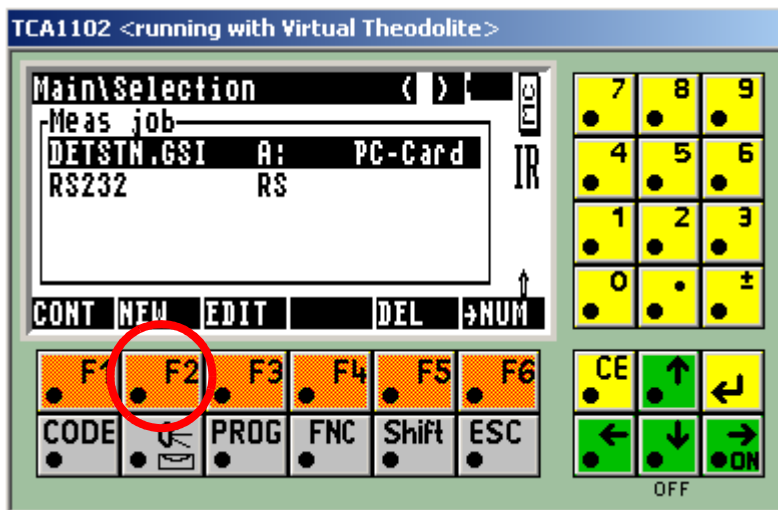

Press F1 to continue

Measured file setup

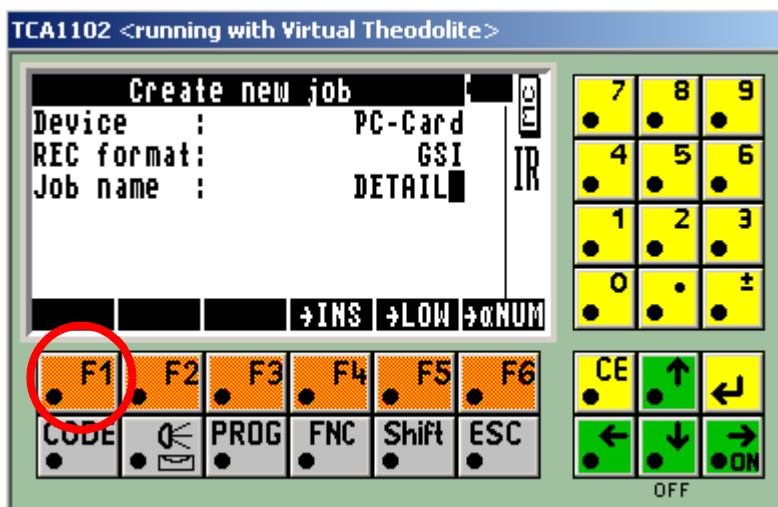

Select 1 to set up Measured job file. This is the file that will contain the detail survey readings

Select F2 to create new file

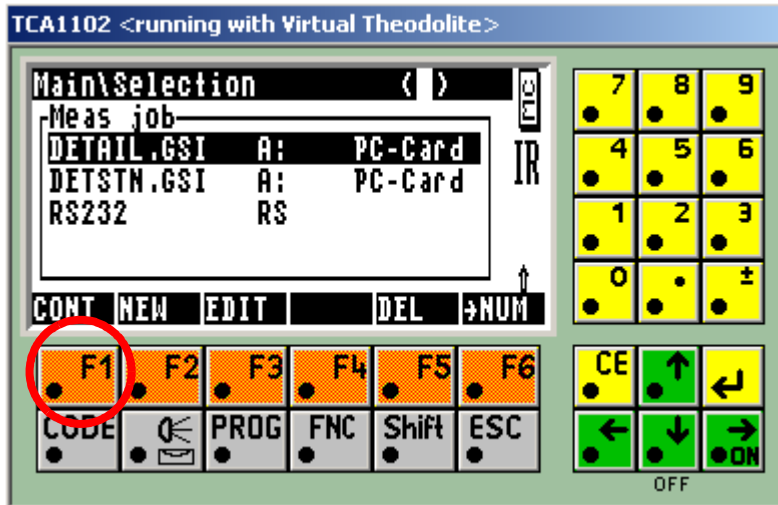

Type in new job name

Press F1 to continue

Press F1 to continue

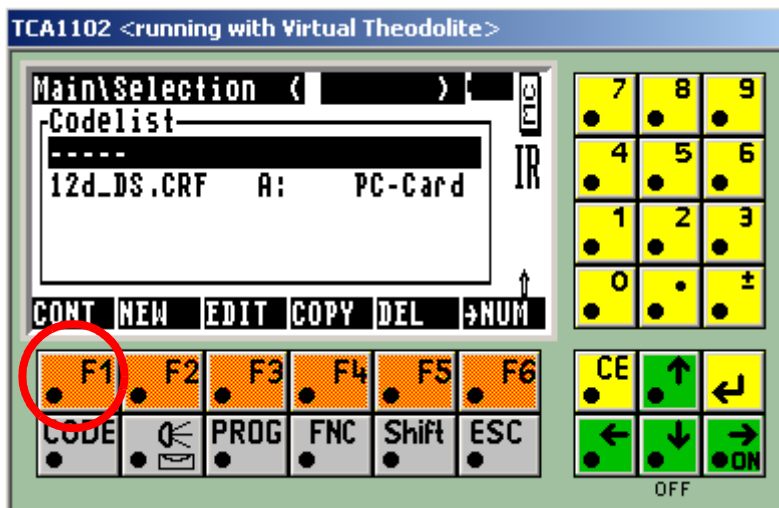

Code list selection

Press 3 to select code list

Select the code list 12D_DS.CRF

Press F1 to continue

Station setup

We can use Quick set (See the section "Setup using Quick set (QSET)") for the station setup or manually select the Station

The following notes assume that the data file contains station coordinates

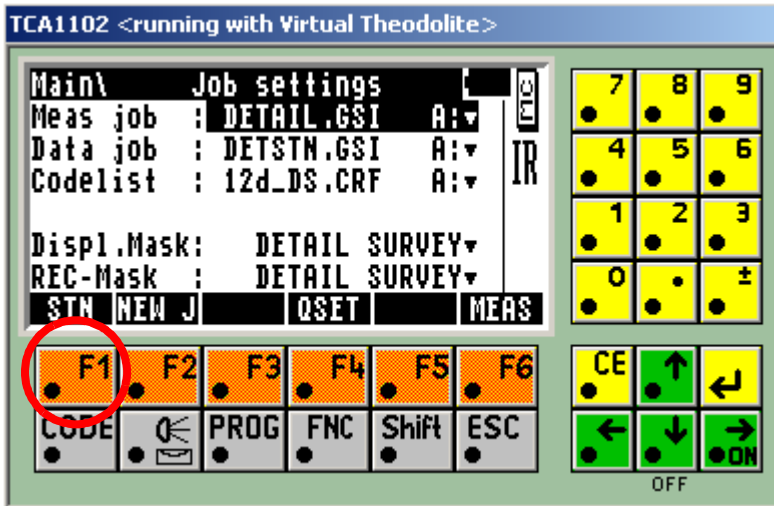

If not the user will have to follow prompts to insert the coordinates

Manual setup

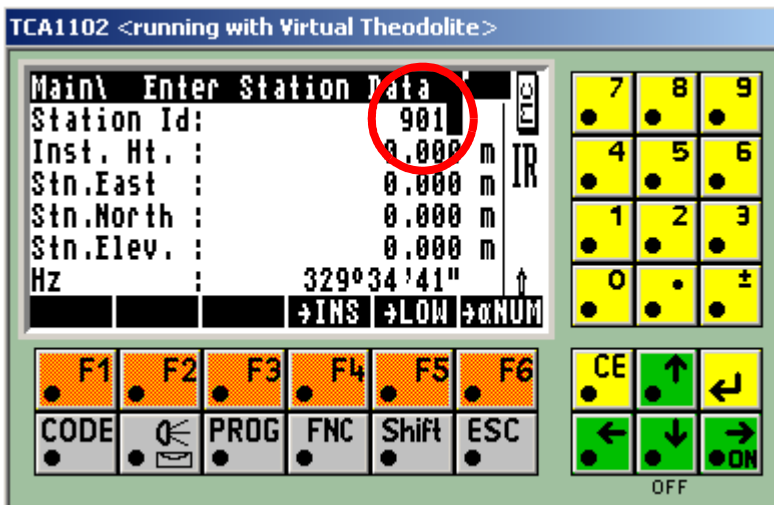

Press F5 for set up

Press F1 to select station

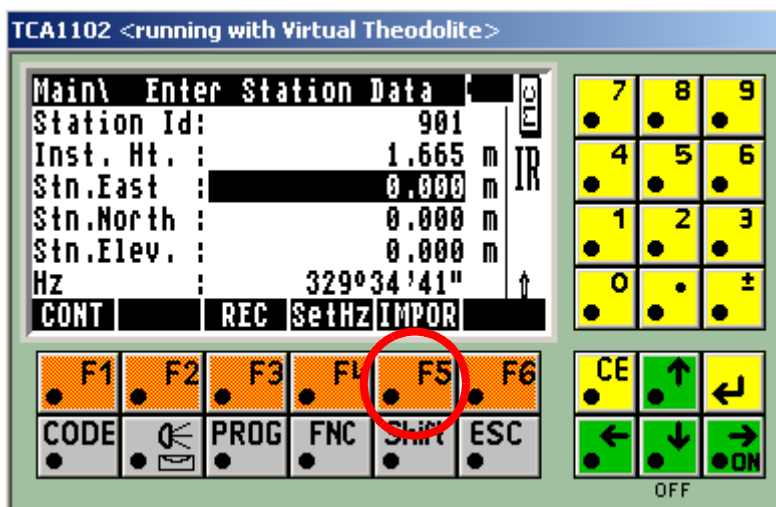

Type in setup station number

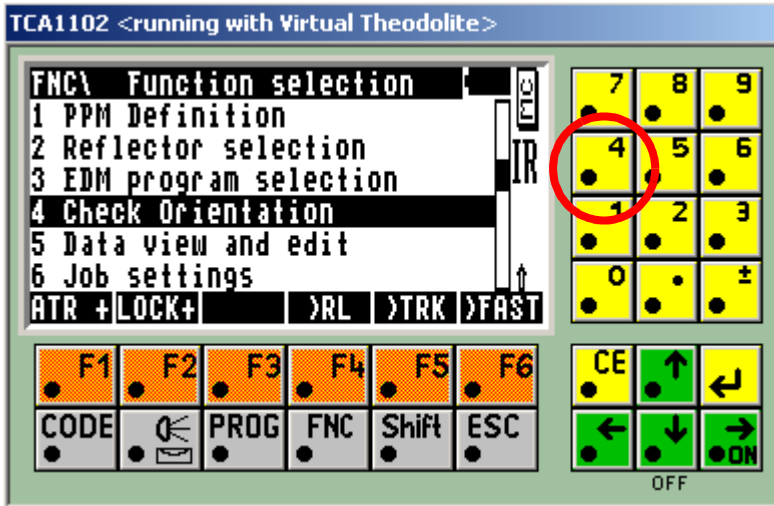

Type in the instrument height

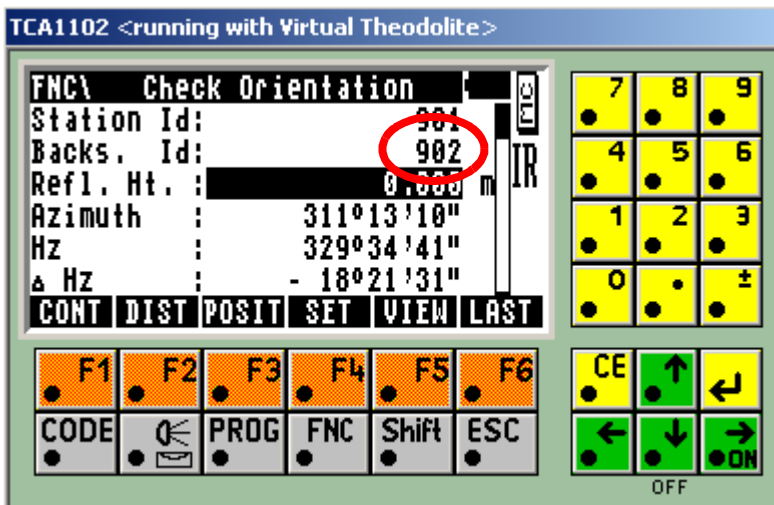

Press F5 to read the coordinates from the data file

To view the bearing between the setup station and backsight station select FNC
 Press 4 to check orientation

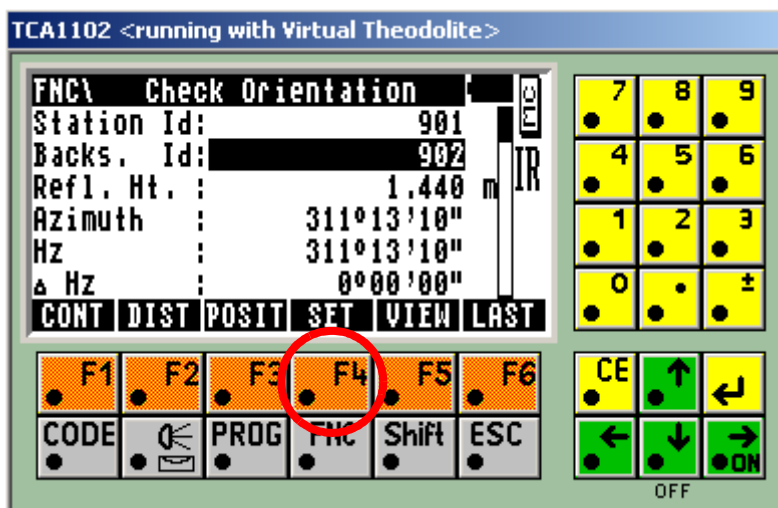

Type in the backsight station number

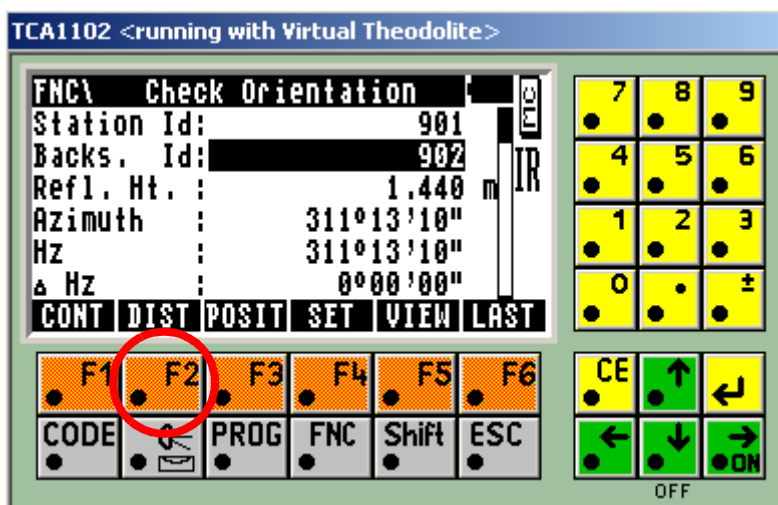

The Azimuth is displayed

Type in the reflector height of the backsight

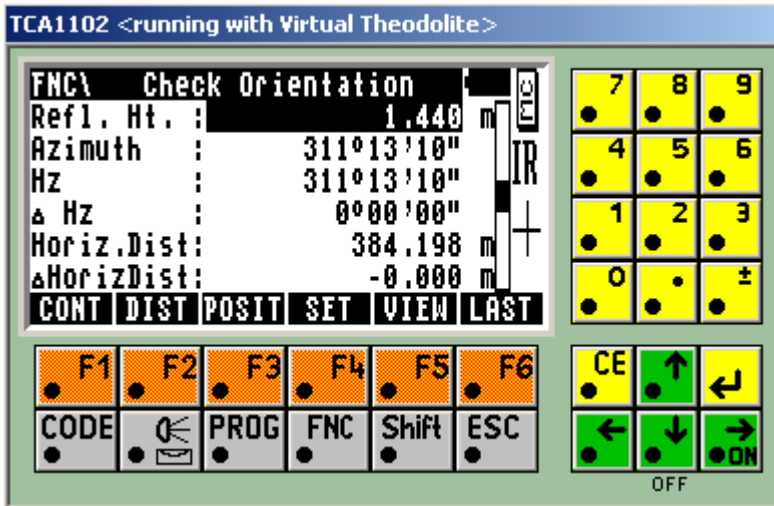

Sight to the backsight station and press F4 to set the bearing

The Bearing is set. Notice that the Azimuth and HZ values are set to the same value. Press F2 to take a distance to the backsight station

Arrow down to view the distance error

If acceptable press F1 to continue

To save the station information press F3 then F1 to continue

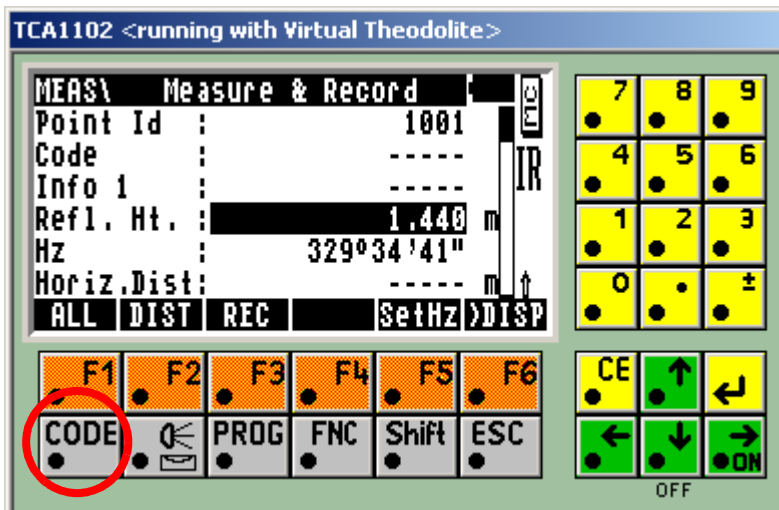

Take Backsight reading:

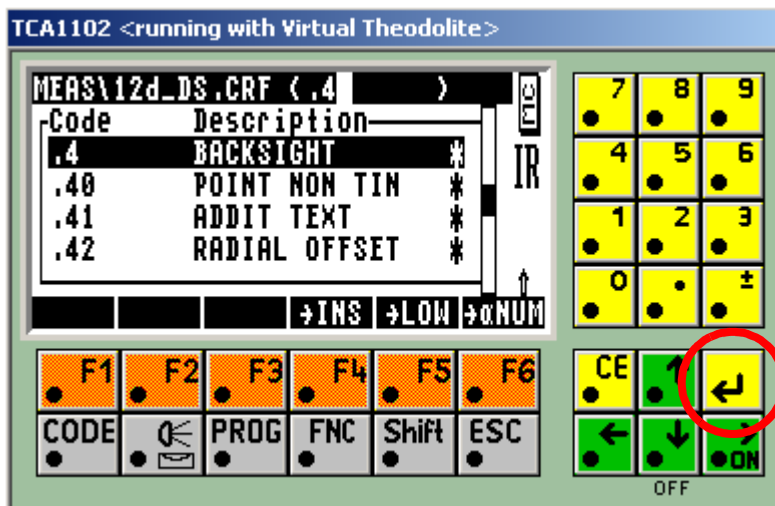

Type in the start point number of the survey

Type in the reflector height. This can also be done as part of the backsight measurement as shown below.

Select CODE

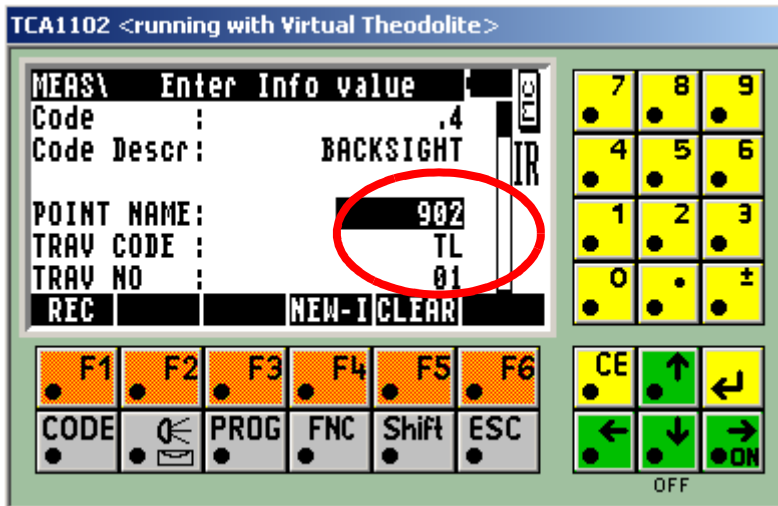

Type in .4 for backsight code followed by the enter key

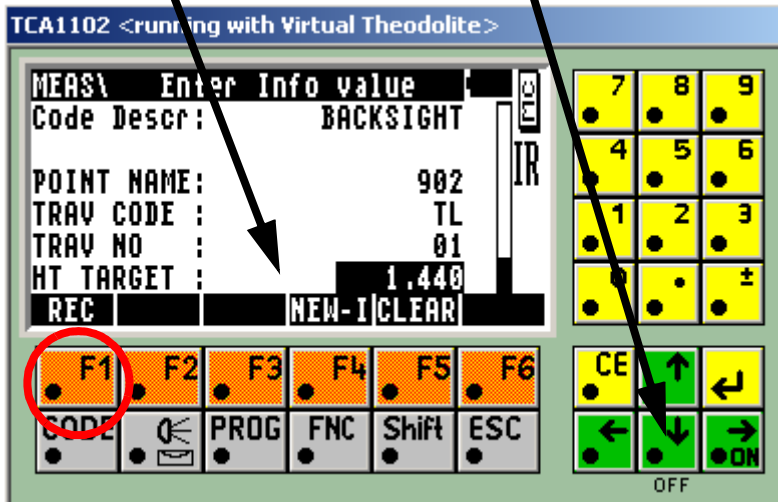

Type in backsight station number

Type in traverse code and traverse no. string number if using traverse coding. For more information about traverse coding see the section "Traverse coding".

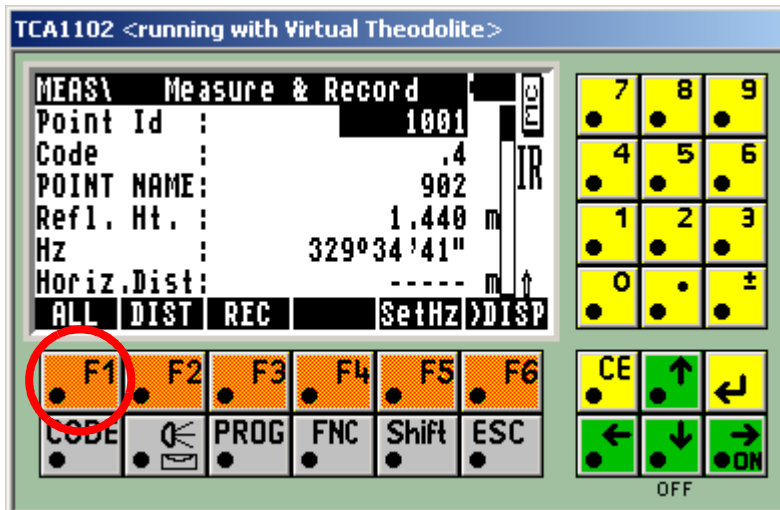

Scroll down using the arrow keys to show other parameters

Press F1 to record the code

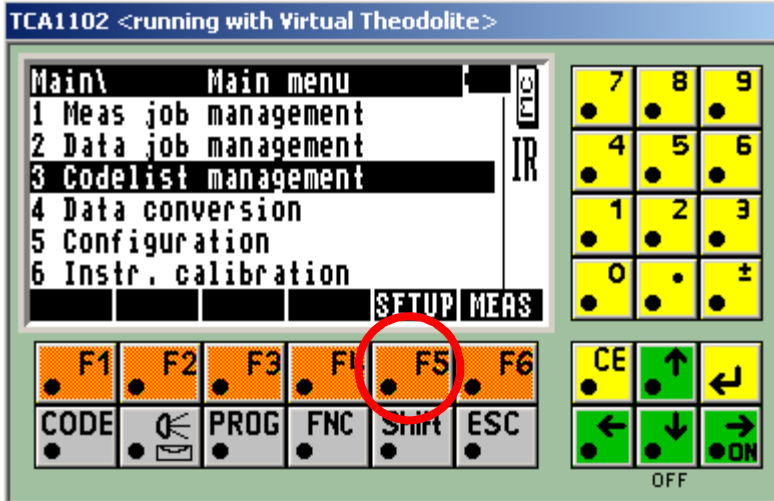

Point to backsight station and press F1 to take and record reading

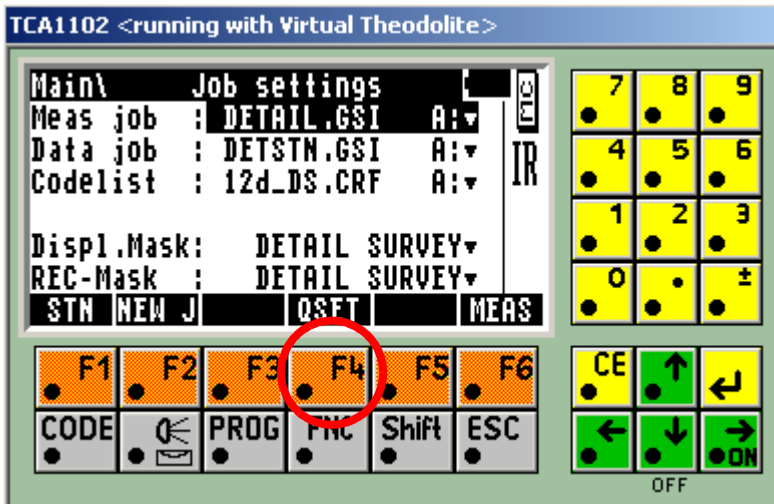

Setup using Quick set (QSET)

IMPORTANT NOTE: If using QSET, you MUST take a check reading to your backsight station as described below.

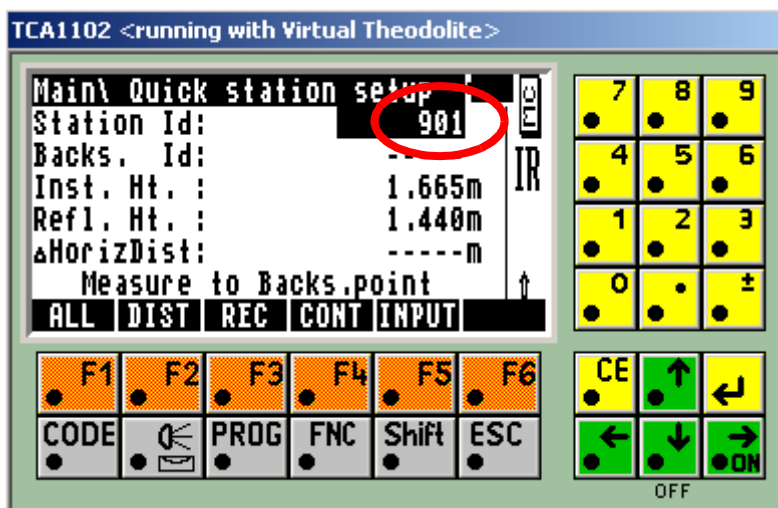

Press F5 for set up

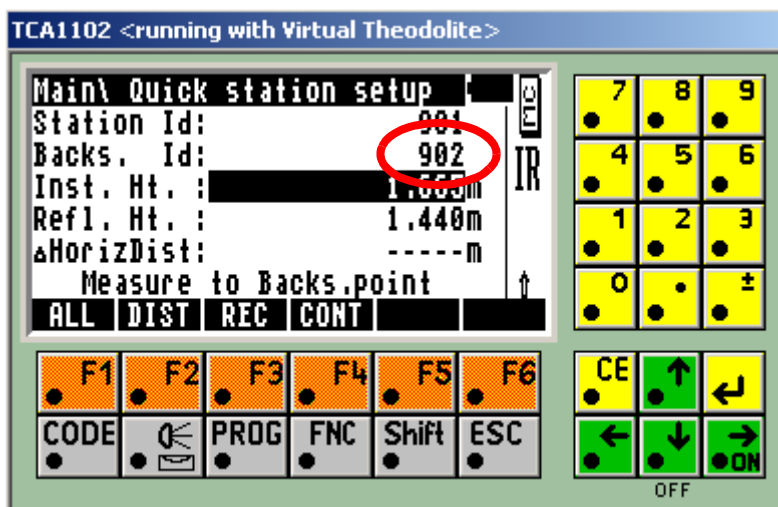

Press F4 for Quick set

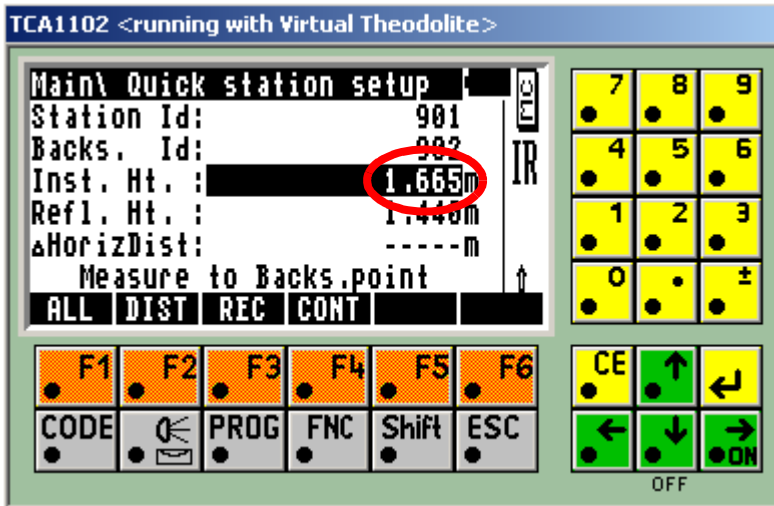

Type in setup station number

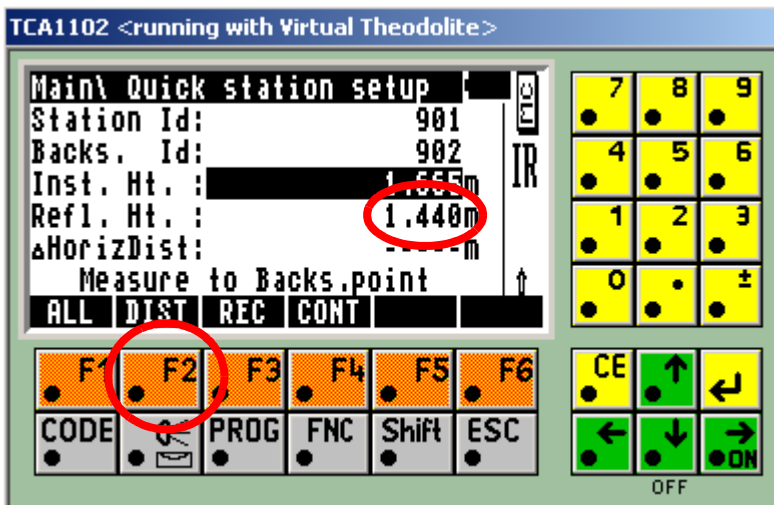

Type in the backsight station number

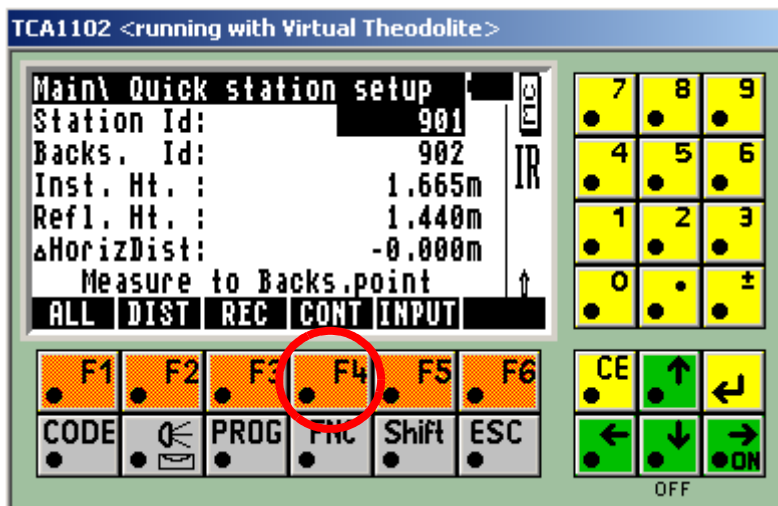

Type in instrument height

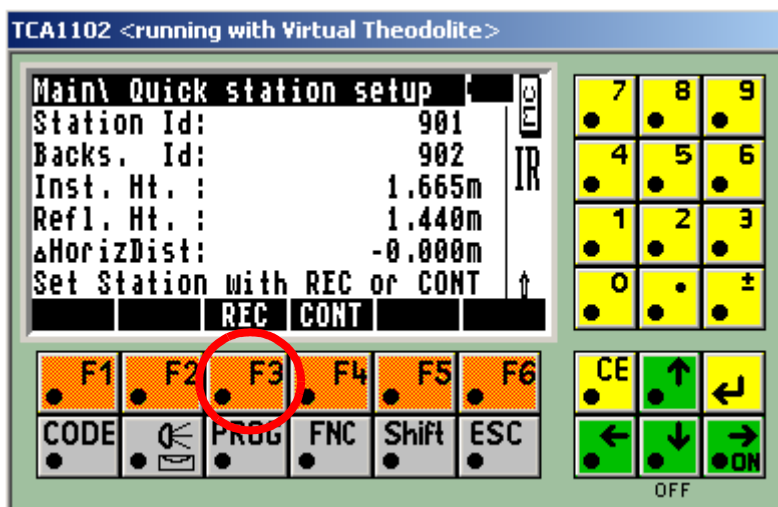

Type in height of target then Press F2 to take reading to backsight to initialise the QSET function.

Press F4 to continue

Press F3 to record the station setup information.

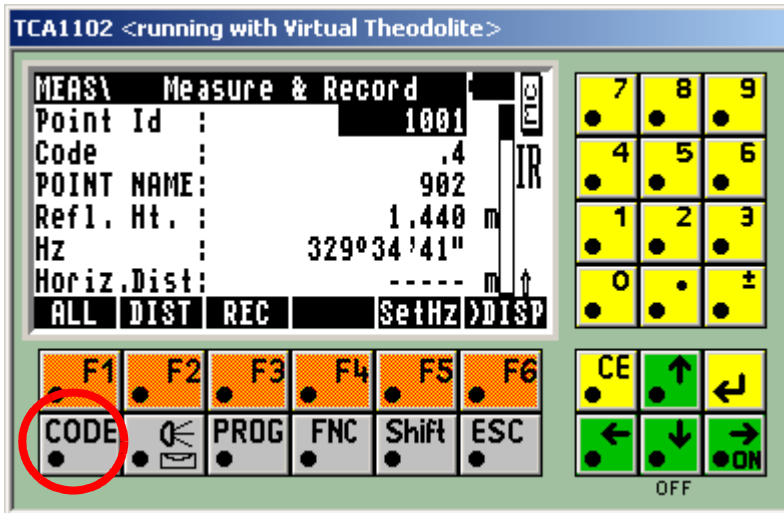

IMPORTANT NOTE: If using QSET, you MUST take a check reading to your backsight station as described below.

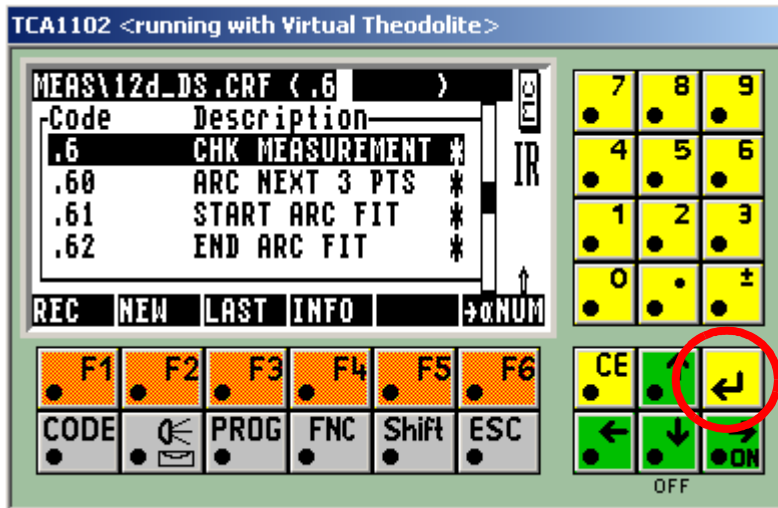

Take Check reading (Mandatory):

Type in reflector height

Select CODE

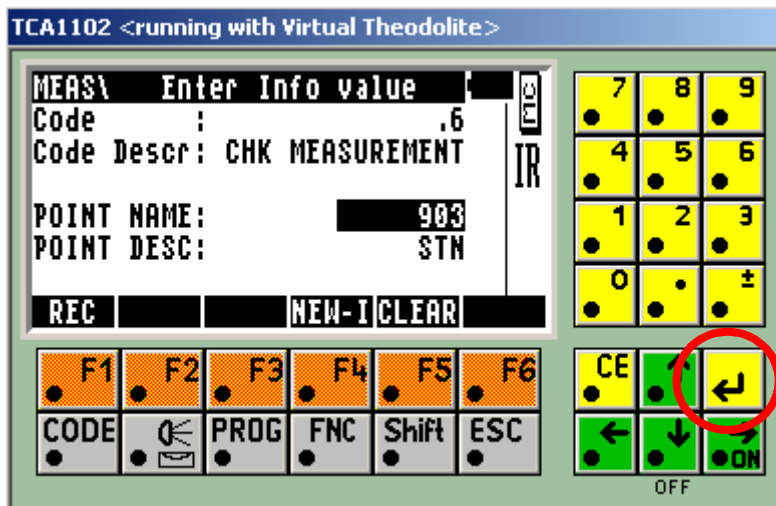

Type in .6 for check measurement code followed by the enter key

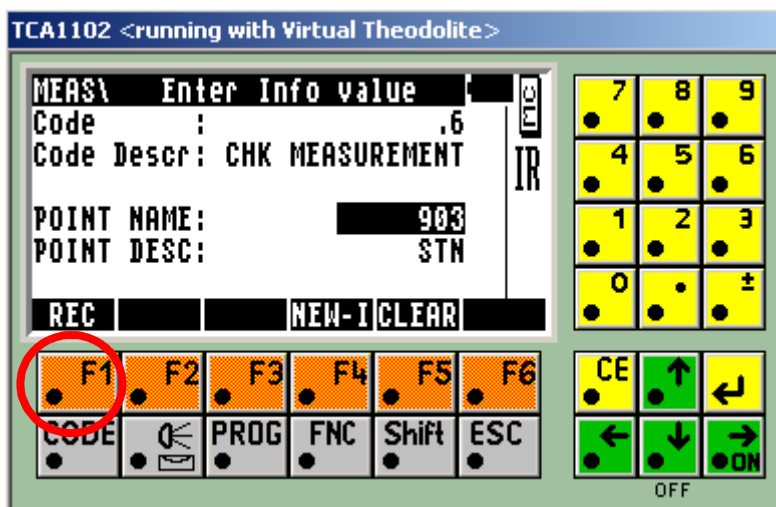

Type in the check station number

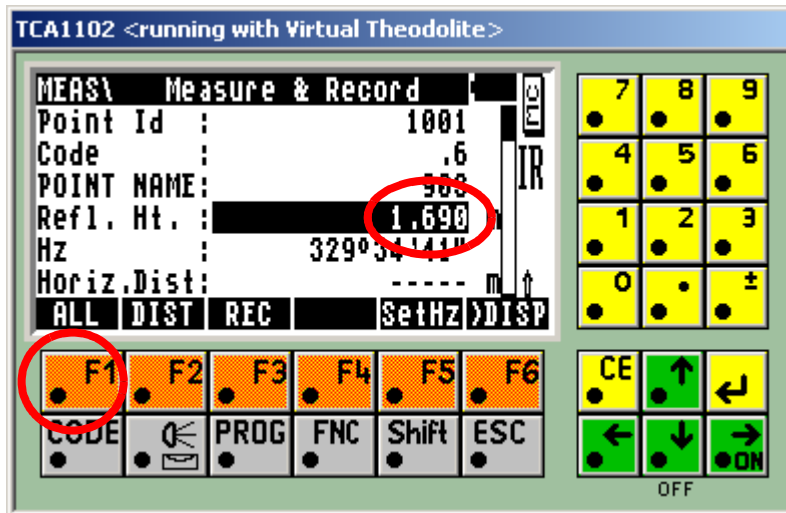

Type in the description

Press F1 to record code

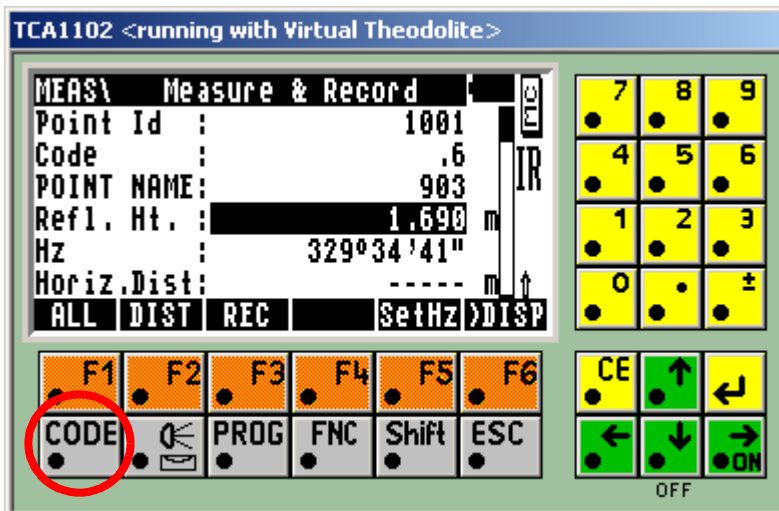

Type in the reflector height

Select F1 to take reading

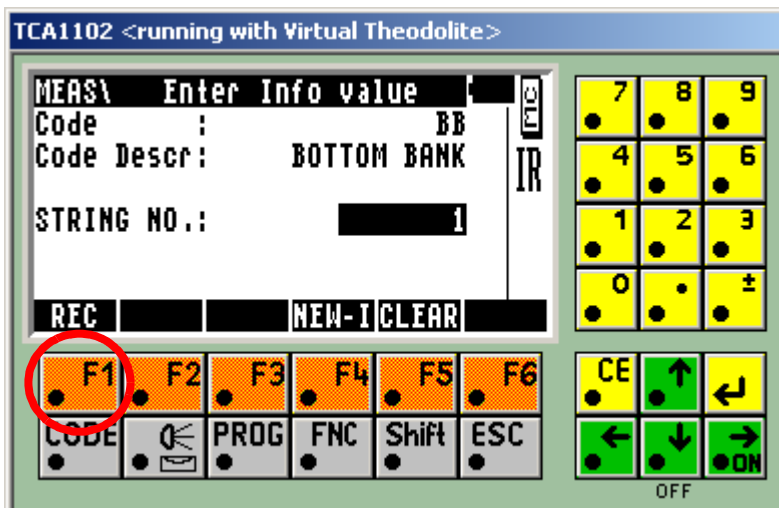

Normal readings

Always change the code prior to starting a new feature and ensure the reflector height is correct

Select Code

Type in the required code and string number

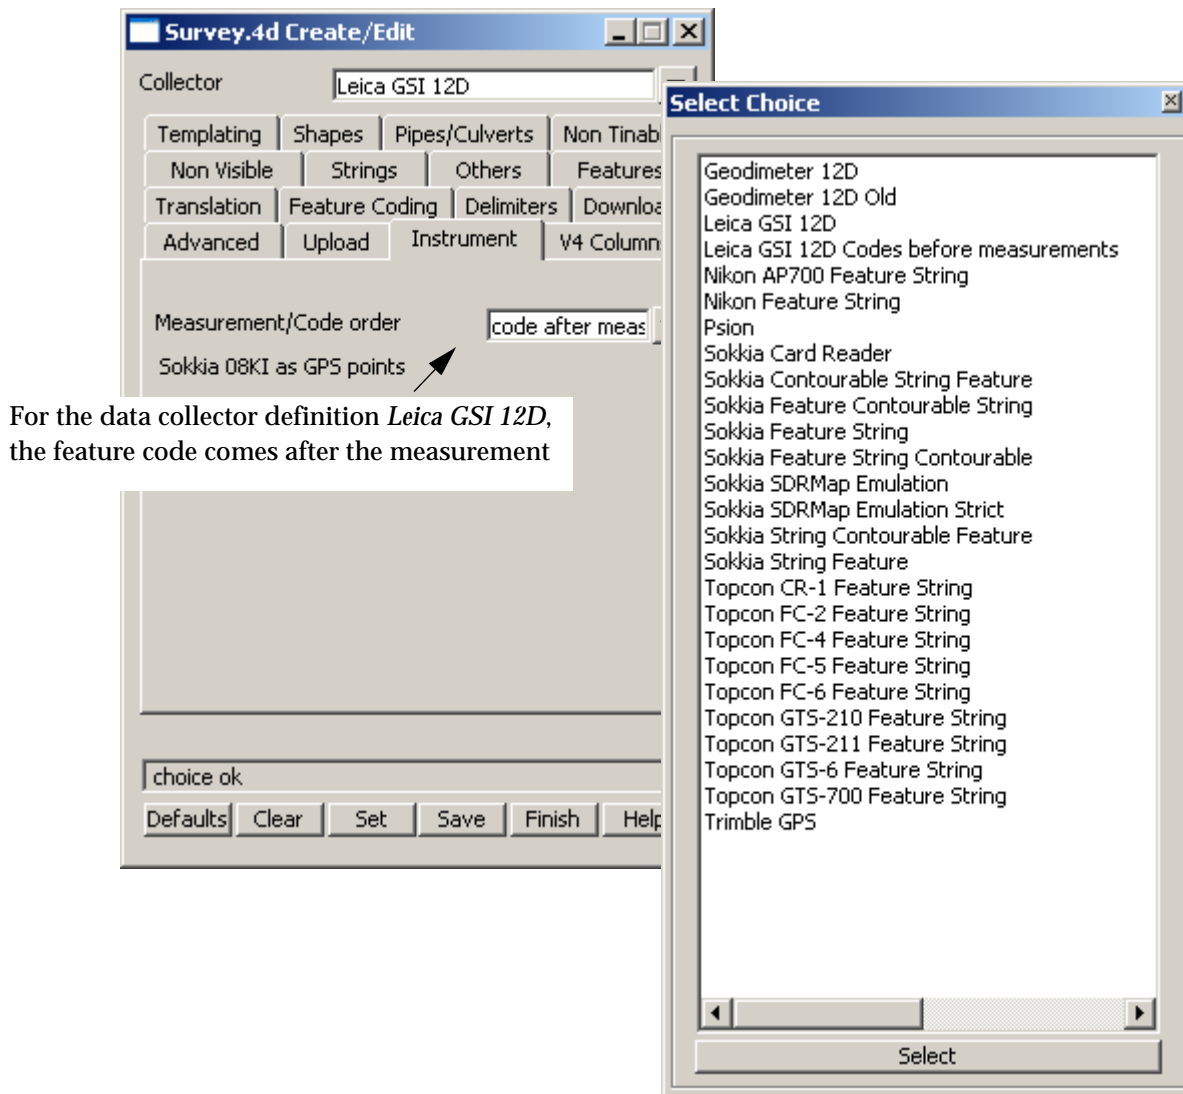

Press F1

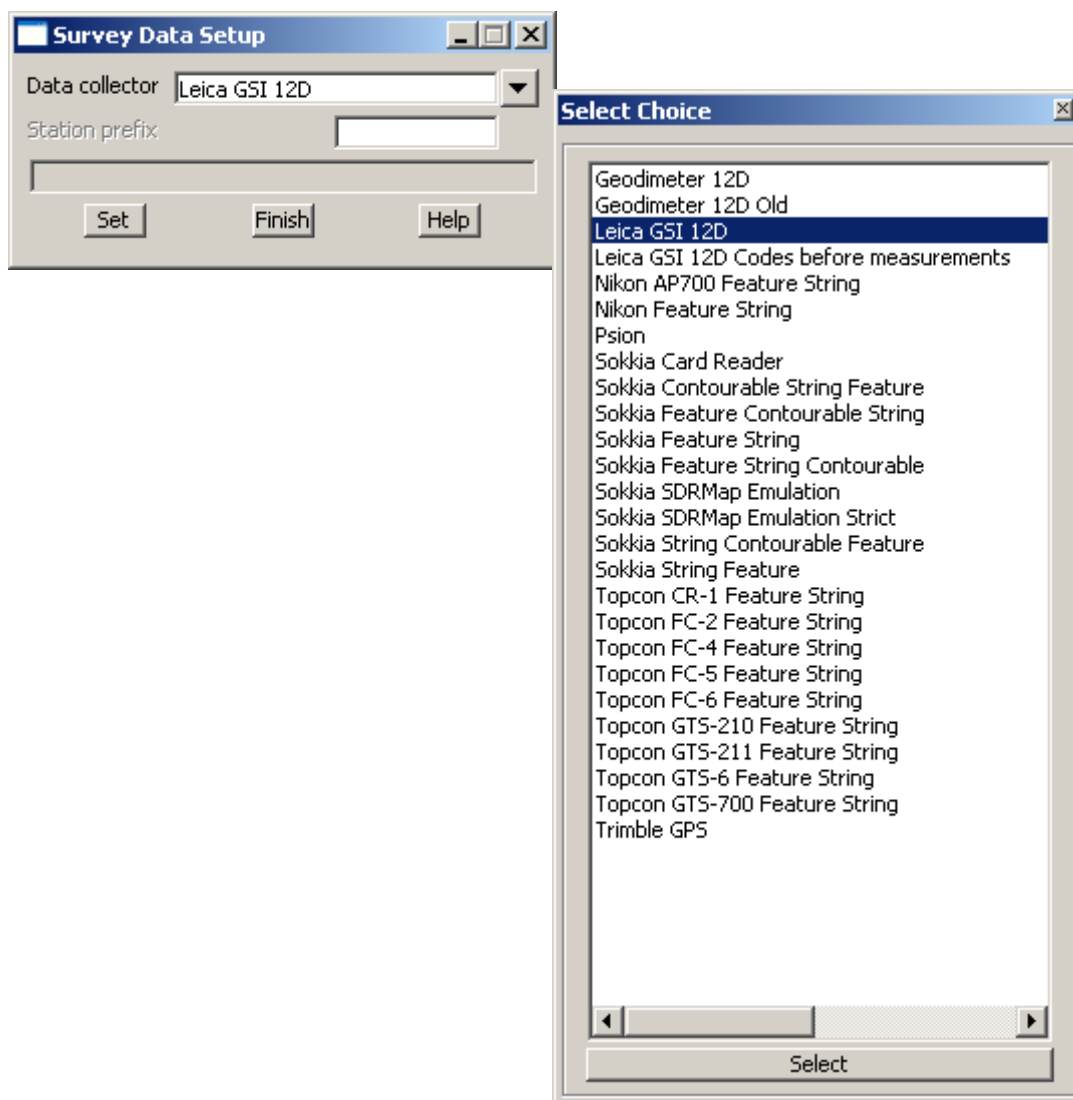

Example of Leica GSI File

The following GSI file has been coded with the Feature Code being recorded after the measurement. The Feature code definition is then applied to all subsequent measurements until another measurement with a following Feature Code definition is found.

The data collector definition *Leica GSI 12D* which is shipped with 12d Model, is an appropriate data collector definition for converting the example GSI file to a 12d Field File ready for processing.

The data collector definition *Leica 12D* which is shipped with 12d Model is selected using the option *Survey=>Setup*

Description**Leica GSI File in 8 Format using 12d Model Field Coding and Giving Feature Codes After a Measurement**

Directly entered co-ords for station 10	410001+000000.2 42....+10000000 43....+10000000 44....+00010000 45....+00000STN 46....+00000000 47....+00000000 48....+00000010
Instrument set-up on 10 with instrument height of 1.715	410002+000000.3 42....+00000010 43....+0001.715
Next measurement is backsight to 931	410003+000000.4 42....+00000931
Measurement to backsight - has point number 1765	110004+00001765 21.324+19135130 22.324+09010170 31..00+00091100 51..1.+0007+000

Measurement - FC RDG SN 1 has point number 1768	110010+00001768 21.324+21820190 22.324+09137140 31..00+00020397 51..1.+0007+000
Measurement - FC RDG SN 1 has point number 1769	110011+00001769 21.324+22104470 22.324+09155360 31..00+00019241 51..1.+0007+000
Measurement - FC RDG SN 1 has point number 1770	110012+00001770 21.324+21747290 22.324+09208580 31..00+00018299 51..1.+0007+000
Close the previous string RDG	410013+00000.20

H Geodetics Summary

Various options in **12d** Model version 7.0, use geodetic calculations to present and change data. These options use terminology that are common to the field of geodetics, which will be defined here.

Most of the terminology adopted follows definitions given in the Australian “**GDA Technical Manual**” which is published by the Intergovernmental Committee on Surveying and Mapping (ICSM). This publication is a valuable reference document and the reader is encouraged to obtain a copy for a full understanding of the topic. The document can be accessed on the internet at the following address <http://www.anzlic.org.au/icsm/gdatm/>

Please continue to the next section “Shape Of The Earth” .

Shape Of The Earth

The determination of the Earth's shape is a science known as **Geodesy**. Today, it is widely accepted that the Earth's shape best approximates an **ellipsoid** that has been revolved around the Earth's polar axis. Put another way, the shape is a sphere that has been squashed at the north and south poles. The non-spherical shape is due to gravity.

A number of ellipsoids have been calculated to best approximate the Earth's shape at local locations and the earth as a whole. The best fit is concerned with matching the Earth's equipotential gravity field (the **Geoid** that is best approximated by Mean Sea Level), to a geometric ellipsoid shape. As such, there a wide number of definitions.

Diagram from: A guide to coordinate systems in Great Britain.
See <http://www.gps.gov.uk/guidecontents.asp>

The most common way of defining an ellipsoid is by describing the **semi-major axis** value and an **inverse flattening** value (this parameter describes the “squashing” of the ellipse).

From GDA
Technical
Manual

Some commonly used ellipsoids are:

Ellipsoid	Semi-major axis	Inverse flattening
GRS80	6,378,137.0	298.257222101

This ellipsoid is used for Australia's GDA definition (Geocentric Datum of Australia GDA 94) used for MGA (Map Grid of Australia) calculations, New Zealand's NZGD2000 datum as well as other geocentric earth model datums around the world.

Ellipsoid	Semi-major axis	Inverse flattening
ANS	638160	298.25

This was the ellipsoid used to define the Australian Geodetic datum (AGD 84) used for AMG (Australian Map Grid) calculations and ISG (Integrated Survey Grid) co-ordinates.

Ellipsoid	Semi-major axis	Inverse flattening
NZ Geodetic 49	6378399.065	297.0

This was the ellipsoid used to define the NZ 1949 Geodetic datum. The semi-major axis given here has been adjusted to compensate for errors in units conversion from links to meters.

Please continue to the next section "Geodetic Coordinates" .

Geodetic Coordinates

Once an ellipsoid or **Geodetic Datum** is defined, a position on the earth's surface can be described in terms of Geodetic coordinates. These coordinates are **Longitude**, **Latitude** and **Ellipsoid height**.

Longitude is an angular quantity measured from the Greenwich meridian. It is most commonly described in terms of degrees, minutes, seconds East or west of the Greenwich meridian.

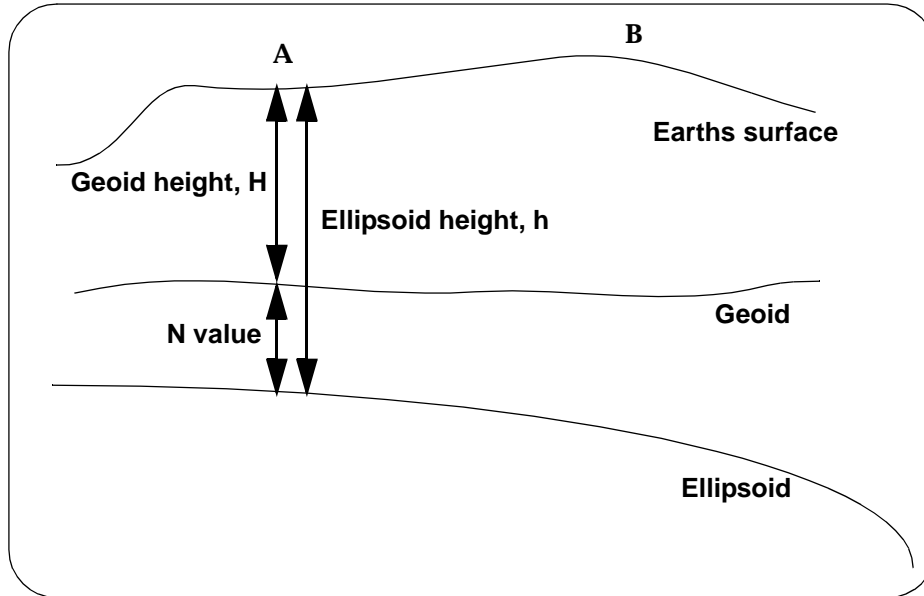

Latitude is an angular quantity measured from the equatorial plane, to the plane defined by the point position and the plumb line to the ellipsoid surface. It is most commonly described in terms of degrees, minutes, seconds South or North to the equator.

The **ellipsoid height**, h is the height above the reference ellipsoid.

Most height datums are not based on ellipsoid height but are based on the **geoid**, e.g. AHD in Australia.

As such, levels from GPS observations (which are **ellipsoid** heights) need to be corrected to a geoidal or orthometric height. To do this, we require the separation or gap distance between the two different surfaces. This separation is known as the **N value**.

The Ellipsoid height = Geoid height + N value, or

$$h = H + N$$

N values can be defined in a geoidal model such as Ausgeoid98 which represents grids of N values over all of Australia. For a given Geodetic coordinate, an N value can be interpolated from the model and applied to the ellipsoid height to give a geoidal height. Similarly, the N value can be used to convert a geoidal height to an ellipsoid height.

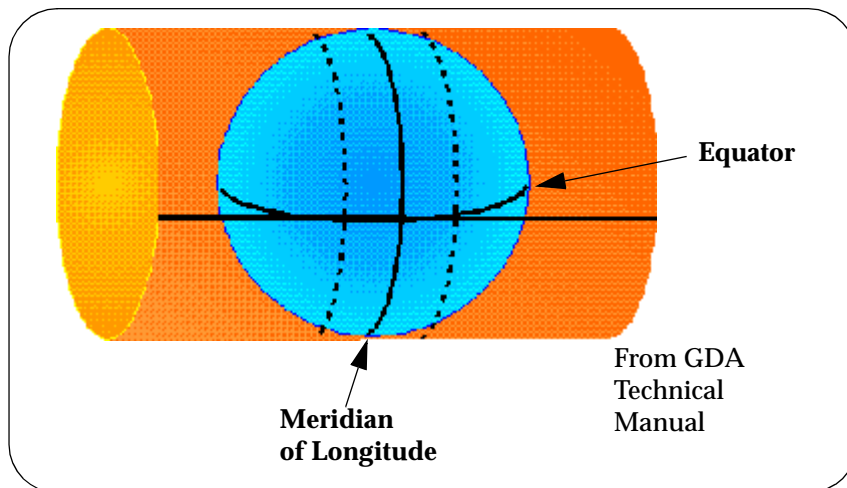

Since most geodetic calculations are made on the ellipsoid, the **ellipsoid height** is required for precise calculations.

Please continue to the next section "Projections".

Projections

In order to represent ellipsoid data on a flat surface for mapping, it is necessary to use a projection. A projection enables points on the earth's surface to be mathematically projected onto an imaginary developable surface. This surface can then be developed or "rolled flat". Typically, this surface is a cylinder or cone.

The Transverse Mercator system (TM) projects coordinates onto a cylinder that is tangent to the equator and the entire length of a meridian of Longitude.

12d Model version 6.0 and above, allows a number of projections to be specified including, Universal Transverse Mercator (UTM), Transverse Mercator (TM) and Rectified Skew Orthomorphic (RSO). There are many more available using the **General** type.

Within 12d Model, a projection can be defined that specifies both the **reference ellipsoid** and **projection type**. This then can be used for geodetic calculations.

A projection has various parameters that define it. These are specific to the projection and are clearly defined for major mapping systems. For example MGA94 zone 56 projection is defined as follows:

Set Projection

Projection name: MGA94 Zone 56

Projection type: UTM

Zone Number: 56

North/South Hemisphere: South

Use known ellipsoid:

Ellipsoid: GRS80

Semi-major axis: 6378137.0

Reciprocal flattening(1/f): 298.257222101

choice ok

Set Finish Help

Please continue to the next section “Terminology” .

Terminology

The various geodetic options in 12d Model mostly use standard geodetic terminology as defined in the Australian GDA technical manual. For clarity, they will be defined again here. For some options it is important to note that some terminology used in Australia has quite a differing meaning in other countries.

Ellipsoid Distance

The **ellipsoid distance** is the reduced distance along the *surface* of the ellipsoid. Standard survey measurements are reduced to the horizontal but require a correction due to the height above the ellipsoid. This is usually done by a **height scale factor** which takes into account the ellipsoid height at each end of the measured line. i.e.

$$\text{HeightScaleFactor} = 1 - \frac{h_M}{R + h_M}$$

Where:

h_M = Mean terrain height (mean of the two ellipsoid heights at either end of the measured line)

R = Radius of the earth in the azimuth of the line.

Note: An error of 60 meters in the value of **h_M** will introduce an error of 10 ppm in the reduced ellipsoid distance. With the introduction of the Australian Geocentric datums, the N values have increased markedly over Australia. So even if a survey is undertaken at sea level (Geoid height approximately 0.0), the ellipsoid heights may very well be greater than 60 meters. As The Ellipsoid height = Geoid height + N value, N values should be considered when reducing measured distances to these datums.

For older Australian ellipsoids, Mean seal level approximated the surface of the ellipsoid (i.e. N value approximately 0.0), so corrections could use geoidal heights to bring the distances down onto the reference surface.

The ellipsoid distance can be calculated using the calculated height factor:

Ellipsoid Distance = Reduced Horizontal Distance x height scale factor.

Bearings and Distances - Plane and Grid

If you have a point on an ellipsoid and a Transverse Mercator projection (such as UTM), the projection co-ordinates are known as the grid co-ordinates of the point (Easting and Northing).

On an *ellipsoid*, the **straight line** joining two points is the **Great circle** between the two points. If each point along the Great circle is projected onto the grid, the path that is traced out is an *arc* between the points.

That is, the *straight lines* on an ellipsoid project onto the TM grid as arcs.

In the diagram below, the Great circle arc through points A and B on the ellipse projects onto the arc shown through Points A and B in grid co-ordinates.

So the *straight line* joining the two points in the **plane** is *different* from the projection of the great circle (straight line on the ellipsoid) joining the two points on the ellipsoid.

Plane Bearing, Projection Bearing

If a straight line is drawn in the plane between two points on a grid, the angle between grid north and this line is equal to the **plane bearing**.

In other words, if the two point's coordinates are known, standard plane trigonometry can be used to calculate the bearing of the line.

$$\tan(\text{plane bearing}) = (E2 - E1) / (N2 - N1)$$

Projection bearing and plane bearing is used interchangeably in 12d Model.

Australian Grid Bearing, Ellipsoid Bearing

In Australia, the **grid bearing** is the angle between grid north and the *tangent* to arc at a point on the arc. e.g Point A. The grid bearing at point A is **not** equal to the reverse grid bearing from point B.

This term is also known as the **ellipsoid bearing** in some countries.

Warning: In some countries, including New Zealand and the US, the term **Grid bearing** is used for the previously defined term **Plane bearing**. However, as defined in the Australian GDA technical manual, the definition of Grid bearing is different to that of a plane bearing.

To avoid confusion, we will use the term **ellipsoid bearing**.

Plane Distance

The **plane distance** is the length in the plane of the straight line joining two points on a grid - that is, the standard distance between two points in a plane

$$\text{plane distance} = \text{square root} [(E2-E1)*(E2-E1) + (N2-N1)*(N2-N1)]$$

Australian Grid Distance

On an ellipsoid, the *straight line* joining two points on the ellipsoid is the Great circle between the two points. The *straight lines* on an ellipsoid project onto the UTM grid as arcs. In the diagram below, the arc shown through points A and B is the projection of the Great circle arc through points A and B on the ellipse.

In Australia, the **grid distance** is the distance on this *arc* from point A to B.

The difference between the plane distance and the grid distance is usually negligible.

Warning: In some countries, the term *grid distance* is used for the definition of plane distance here.

Datum

Within the Geodetic sections of 12d Model, the term **datum** relates to the reference ellipsoid adopted by countries/organisations for mapping projects.

For example AGD is the Australian Geodetic Datum, using the ANS ellipsoid parameters. GDA refers to the Geodetic Datum of Australia, using the GRS80 ellipsoid as the basis for defining geodetic coordinates.

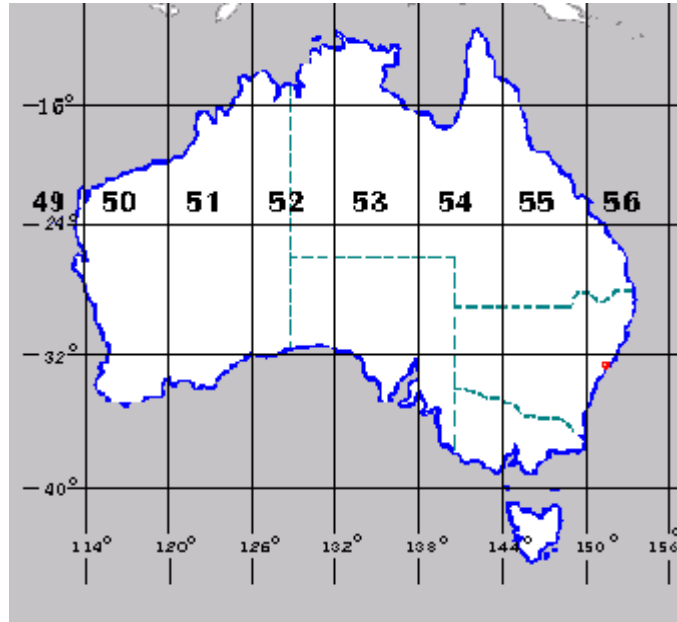

In New Zealand, the NZGD49 datum refers to the NZ Geodetic 49 ellipsoid. The NZGD2000 datum is the New Zealand geodetic datum which again refers to the GRS80 ellipsoid.

Zone

The meaning of **zone** is specific to the UTM projection type which is commonly used around the world as a mapping projection. This includes AMG and MGA in Australia.

The Universal Transverse Mercator projection splits the world into 60 zones of 6 degrees of longitude. The zone numbering starts at 180 degrees West, longitude. Each zone has a specific central meridian and range of longitude that defines it. As such, by supplying a zone number, a number of parameters about a projection can be deduced.

For example, Australia is covered by the UTM zones 49 to 56.

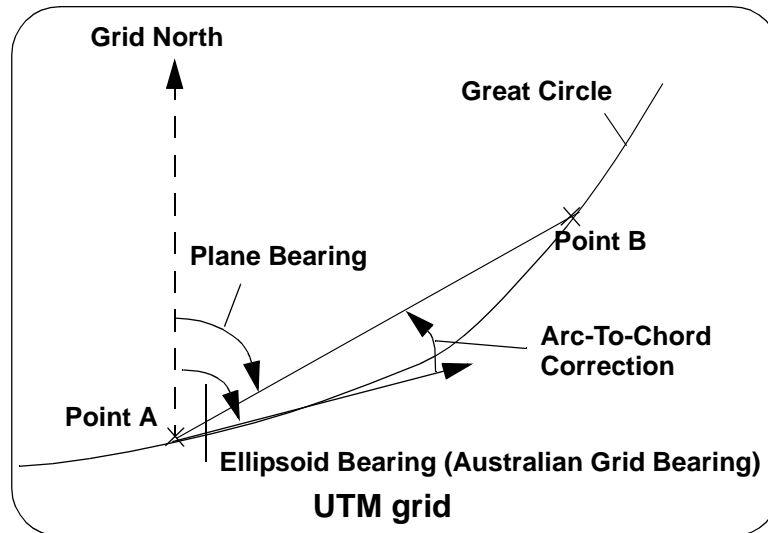

Arc-to-Chord Correction (t-T correction)

The **arc-to-chord** correction is the quantity to be added algebraically to a ellipsoid bearing (Australian grid bearing) to obtain a plane bearing.

$$\text{Plane Bearing} = \text{Ellipsoid Bearing} + \text{Arc-To-Chord Correction}$$

$$\text{Plane Bearing} = \text{Australian Grid Bearing} + \text{Arc-To-Chord Correction}$$

This correction is only really applicable for lines over 10 km but it is included in calculations for completeness. The correction shown in the example below is negative in sign but it can also be positive.

Point Scale Factor

The **point scale factor** is the ratio of an infinitesimal plan distance at a point on a grid to a corresponding ellipsoid distance.

It can be used as an approximation to convert (factor) measured ellipsoid distances to plane distances.

Line Scale Factor

The **line scale factor** is the ratio of the plane distance on a grid to a corresponding ellipsoid distance. i.e.

$$\text{LineScaleFactor} = \frac{\text{PlanDist}}{\text{EllipsoidDist}}$$

This factor can be used to calculate either the plane or ellipsoid distance given the Line Scale Factor and the other distance. i.e.

$$\text{Plane distance} = \text{Ellipsoid distance} \times \text{Line scale factor},$$

Similarly,

$$\text{Ellipsoid distance} = \text{Plane distance} / \text{Line scale factor}.$$

Combined Point Scale Factor

The **combined point scale factor** is the product of the point scale factor and the height scale factor. i.e.

$$\text{Combined Scale Factor} = \text{Point Scale Factor} \times \text{Height Scale Factor.}$$

Azimuth and Convergence

Azimuth is the horizontal angle measured from an *ellipsoidal meridian clockwise from north* and the great circle between measured points.

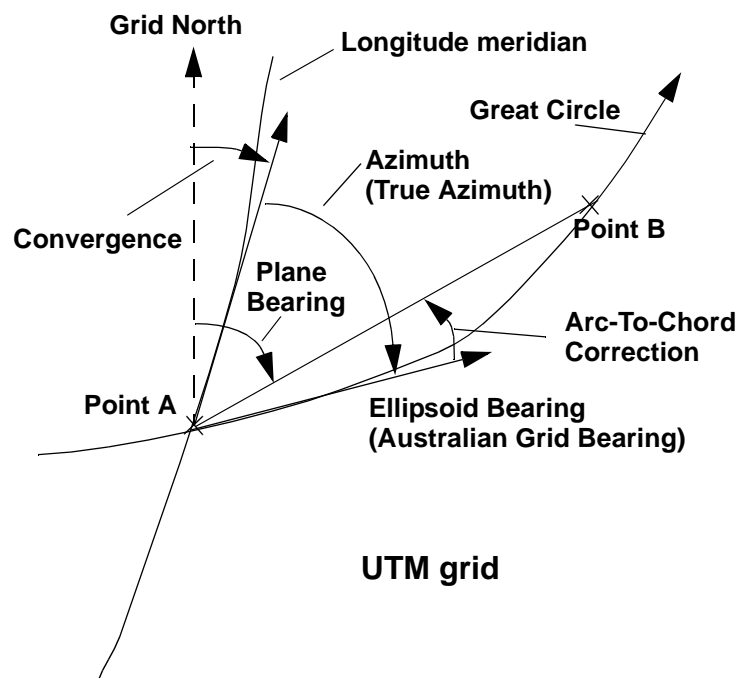

It is also known as the **True Azimuth**. In general, this value will be calculated internally in **12d** Model.

Convergence or **Grid Convergence** is the angular quantity to be added algebraically to an *Azimuth* to obtain an ellipsoid bearing (Australian grid bearing). i.e.

$$\text{Ellipsoid Bearing} = \text{Azimuth} + \text{Grid Convergence}$$

$$\text{Australian Grid Bearing} = \text{Azimuth} + \text{Grid Convergence}$$

Warning: In some countries, the *Grid Convergence* has the opposite sign.

Combining

$$\text{Ellipsoid Bearing} = \text{Azimuth} + \text{Grid Convergence}$$

$$\text{Australian Grid Bearing} = \text{Azimuth} + \text{Grid Convergence}$$

and

$$\text{Plane Bearing} = \text{Ellipsoid Bearing} + \text{Arc-To-Chord Correction}$$

Plane Bearing = Australian Grid Bearing + Arc-To-Chord Correction

produces the equation

Plane Bearing = Azimuth + Grid Convergence + Arc-To-Chord Correction

or

Azimuth = Plane Bearing - Grid Convergence - Arc-To-Chord Correction

True Azimuth = Plane Bearing - Grid Convergence - Arc-To-Chord Correction

Warning: In some countries, the *Grid Convergence* has the opposite sign.

Please continue to the next section “Converting Between AMG, ISG and MGA” .

Converting Between AMG, ISG and MGA

In Australia the ellipsoid used to represent the shape of the earth used to be defined by AGD 84 but it has now been changed to an ellipsoid that has its centre at the centre of mass of the earth (geocentric - GDA 94). See "Shape Of The Earth" .

This is to fit in with GPS because satellites orbits are centred on the centre of mass.

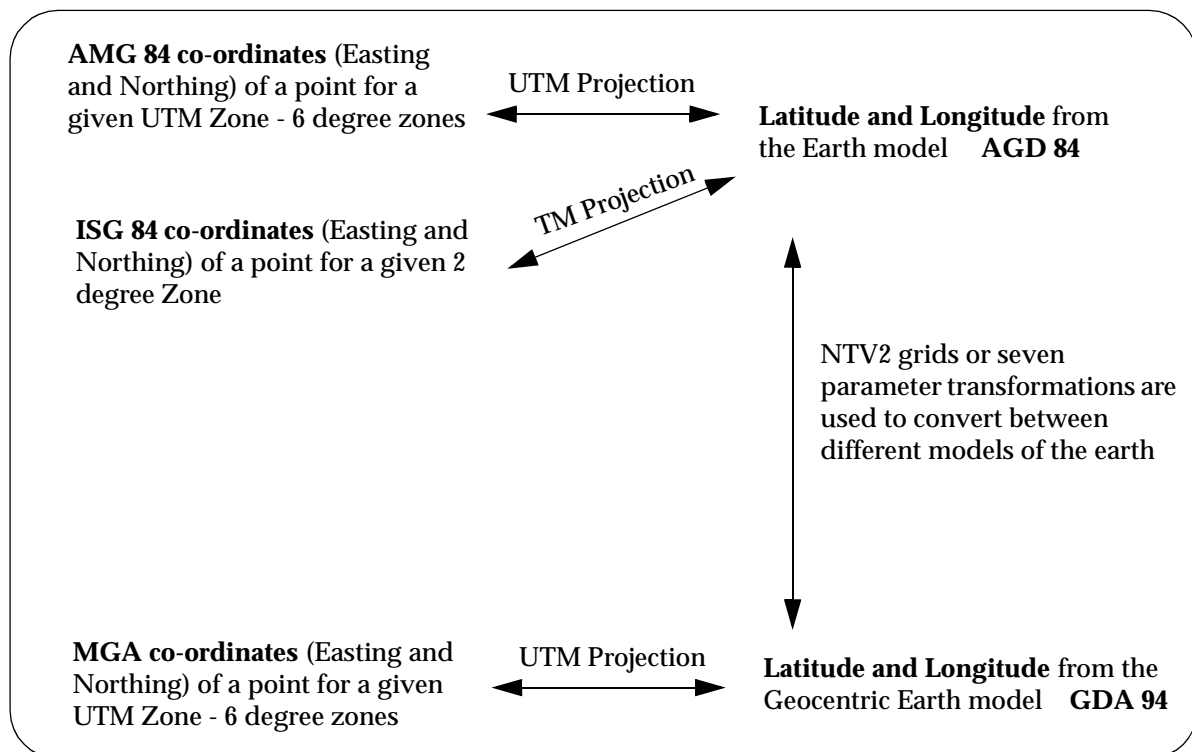

This means that the Latitude and Longitude of every point has changed.

The use of UTM projections (Universal Transverse Mercator - see "Projections") and Zones still apply but because the latitude and longitude of each point has change, its Easting and Northing for a UTM zone has also changed.

AMG 84 Zones are the co-ordinates for the UTM Projections defined for six degree zones using the ellipsoid defined by AGD 84.

MGA 94 Zones are the co-ordinates for the UTM Projections defined for six degree zones using ellipsoid define by GDA 94.

Note - ISG 84 Zones are the co-ordinates for the TM Projections defined for two degree zones using the ellipsoid defined by AGD 84.

For converting between the **different datums** AGD66/84 and GDA94 (i.e. AMG, ISG, Long Lat <-> MGA, Long Lat), use the option

Survey =>Conversions =>AGD66/84 <-> GDA94 (see "AGD66/84 <---> GDA94" in the chapter "Survey")

For converting between different AMG Zones (AMG <->AMG) or different MGA Zones (MGA<->MGA) use the option

Survey =>Conversions =>Australian conversions see "Australian Conversions"

in the chapter "Survey").

For converting between different ISG/AMG Zones (AMG,ISG <->AMG, ISG)

Survey =>Conversions =>Cartographic see "Cartographic"

in the chapter "Survey").

I 12d Ascii File Format

The 12d Ascii file format (called 4D Ascii in Version 4 and earlier) is a text file definition from 12D Solutions which is used for reading and writing out string data from 12d Model. 12d Ascii files normally end in '.12da'

This document is for the 12d Ascii file format used in *12d Model Version 7*.

General Comments about 12d Ascii File

//

Anything after // until the end of the line is ignored. This is used to place comments in the file.

Blank lines

Unless they are part of a text string, blank lines are ignored.

Spaces

Unless enclosed in quotes ("), more than one consecutive space or tab is treated as one space. Except when it is the delimiter after a //, an end of line (<enter>) is also considered a space.

Spaces and special characters in text strings

Any text string that includes spaces and any characters other than a to z, A to Z or 0 to 9 (alphanumeric), must be enclosed in double quotes. In text strings, double quotes " and backslash \ must be preceded by a \. For example, \" and \\ define a " and a \ respectively in a text string.

Names of models, tins, styles, colours and attributes

Models, tins, styles (linestyles), colours and attributes can include the characters a to z, A to Z, 0 to 9 (alphanumeric characters) and space. Leading and trailing spaces are ignored. The names can be up to 255 characters in length. If the name includes spaces, the name must be enclosed in double quotes (").

The names for models, tins, styles, colours or attributes can not be blank.

The names for models, tins, styles and colours can contain upper and lower alpha characters which are stored, but the set of model names, tin names, style names, colour names or attribute names for an object *must be unique when case is ignored*. For example, the model name "Fred" will be stored as "Fred" but "FRED" is considered to be the *same* model name as "Fred".

String names

String names can include the characters a to z, A to Z, 0 to 9 (alphanumeric characters), space, decimal point (.), plus (+), minus (-), comma (,), open and closed round brackets and equals (=). Leading and trailing spaces are ignored. String names can be up to 255 characters in length. If the string name includes anything other than alphanumeric characters, then the name must be enclosed in double quotes (").

String can contain upper and lower alpha characters which are retained but case is ignored when selecting by string name. That is, the string name "Fred" will be stored as "Fred" but "FRED" is not considered to be a different name.

String names do not have to be unique and can be blank.

Please continue to the next section "Attributes".

Attributes

Many 12d Model objects (such as individual strings, models and tins) can have an unlimited number of named **attributes** of type integer (numbers), real and text. Within an object, the attribute names must all be different.

The attributes for an object are given inside the curly braces of the **object** definition. The attributes are preceded by the **attributes** keyword followed by the *named attributes* enclosed in curly braces { and }.

The format for each named attribute is

```
attribute_type      attribute_name      attribute_value
```

where attribute_type is integer, real or text
and attribute_name is the unique attribute name for the object
and attribute_value is the either a number, a real or a text string.

That is the attributes are defined in a block:

```
attributes {  
  integer      att_name      number  
  real        att_name      value  
  text       att_name      text  
}
```

The *text* for a text attribute can be blank an if so, is defined as "".

An example of defining attributes is:

```
attributes {  
  text      "pole id"      "QMR-37"  
  text      street      "477 Boundary St"  
  real      "pole height"  5.25  
  integer   "pole wires"   3  
}
```

Please continue to the next section "Commands".

Commands

Commands consist of a *keyword* followed by a space and then a *value* (a keyword and its value is often referred to as a keyword pair). A *value* must always exist.

```
keyword    value                // a keyword pair
```

There can be more than one command keyword pair per line as long as each keyword pair is separated by a space. In fact, the *keyword* can be on one line and the *value* on the next line.

Although the names of commands are only shown in lower case in these notes, commands are case insensitive and all combinations of case are recognised as the same command. That is 'model', 'MODEL' and 'Model' are all recognised as the command 'model'.

The commands in the 12d Ascii file are:

```
model  model_name                //          system default  data
```

All strings following until the next **model** keyword are placed in the model *model_name*. This can be overridden for a string by a **model** command inside the string definition.

If the model includes attributes, the following *model* definition must be used.

```
model {
  name  model_name
  ...
}
```

All **12d** Model *models* can have an unlimited number of named **attributes** of type integer (numbers), real and text. Within a model, the attribute names must all be different.

The definition for a model with attributes is the **model** keyword followed by information enclosed in curly braces { and }. The keyword *name* followed by the *model_name* **must** be included inside the curly braces.

```
name      model_name
```

The attributes for the model are also specified inside the curly braces of the **model** definition. As described previously, the attributes are preceded by the **attribute** keyword followed by the named attributes enclosed in curly braces { and }.

Hence the *model* definition with attributes is:

```
model {
  name      model_name
  attributes {
    attribute_type  attribute_name  attribute_value
    attribute_type  attribute_name  attribute_value
    ...
    attribute_type  attribute_name  attribute_value
  }
}
```

For example:

```
model {
  name      "telegraph poles"

  attributes {
    text      "pole id"          "QMR-37"
    text      "street"          "477 Boundary St"
    real      "pole height"     5.25
    integer   "pole wires"     3
  }
}
```

```

}
colour colour_name // system default red

```

All strings following until the next **colour** keyword have colour *colour_name*. This can be overridden for a string by a **colour** command in the string definition.

```

style style_name // system default 1

```

All strings following until the next **style** keyword have style *style_name*. This can be overridden for a string by a **style** command in the string definition.

```

breakline point or line // system default line

```

All strings following that requires a breakline point-line type until the next **breakline** keyword, have this point-line type. This may be overridden for the string by a **breakline** in the string definition.

```

null value // system default -999

```

All z-values equal to *value* in strings following until the next **null** keyword, are considered to be null z-values.

```

string string_type {
  ...
}

```

The *string_type* is compulsory and must be followed by all the string information enclosed in curly braces { and }.

Thus if a string type or possibly information inside the string is not recognised, the 12d Ascii reader has a chance of being able to jump over the string by looking for the end marker }.

Inside the braces are **string commands** as keyword pairs defining some information for the string.

There can be more than one *string command* keyword pair per line as long as each keyword pair is separated by a space. In fact, the *keyword* can be on one line and the *value* on the next line.

Any unrecognized *string commands* are ignored.

The *string command keyword pairs* include **model**, **colour**, **style** and **breakline** which are all *optional* inside the string definition. However if any of them exist inside a string definition, then the *string command keyword* overrides any **model**, **colour**, **style** or **breakline commands** but only for that particular string.

For some string types (e.g. 2d, 3d, pipe) there is more data required than just the *string command* keyword pairs.

This extra data is contained in blocks consisting of a *keyword* followed by the required information enclosed in curly braces { and }. For example attributes for all string types and (x,y) data for a 2d string.

For all string types, if there is not enough recognised information to define the string, the string is ignored.

The definition of each *string type* and the allowed *string commands* and extra data for that string type will be given after the next section on string attributes.

string attributes

All 12d Model strings can have an unlimited number of named **attributes** of type integer (numbers), real and text. Within a string, the attribute names must all be different.

The attributes for a string are given inside the curly braces of the **string** definition. As described previously, the attributes are preceded by the **attributes** keyword followed by the named attributes enclosed in curly braces { and }.

Please continue to the next section "12d Ascii Definition for each String Type" .

12d Ascii Definition for each String Type

2d String

```
string 2d {
  z value chainage start_chainage
  model model_name name string_name
  colour colour_name style style_name
  breakline point or line
  data { // keyword
    x-value y-value
    " "
    " "
  }
}
```

3d String

```
string 3d {
  chainage start_chainage
  model model_name name string_name
  colour colour_name style style_name
  breakline point or line
  data { // keyword
    x-value y-value z-value
    " " "
    " " "
  }
}
```

4d String

```
string 4d {
  angle value offset value raise value
  worldsize value or papersize value or screensize value
  chainage start_chainage
  model model_name name string_name
  colour colour_name style style_name
  breakline point or line
  textstyle text slant degrees xfactor value
  justify "top/middle/bottom-left/centre/right"
  data { // keyword
    x-value y-value z-value text // text can not be blank
    " " " " // use "" for no text.
    " " " "
  }
}
```

Alignment String

In an alignment string the horizontal and vertical geometry are given separately and both can only be defined by the intersection point method (IP's).

For the horizontal geometry, the (x,y) position of the horizontal intersection points (HIPs) are given in the order that they appear in the string, plus the circular radius and left and right spirals length on each HIP.

Hence a horizontal intersection point is given by either

```
x-value y-value radius // circular curve, no spirals
or
```

```
x-value y-value radius spill left-spiral-length spil2 right-spiral-length
```

radius, left-spiral-length, right-spiral-length can be zero (meaning they don't exist).

For the vertical geometry, the (chainage,height) position of the vertical intersection points (VIPs) are given in increasing chainage order, plus either the radius of the circular arc or the length of the parabolic curve on each VIP.

Hence for a vertical intersection point is given by either

```
ch_value z-value length parabola
or
```

```
ch_value z-value radius circle
where
```

the word *parabola* is optional. *length* and *radius* can be zero, meaning that the parabola or arc doesn't exist.

```
string alignment {
  model model_name name string_name
  colour colour_name style style_name
  chainage start_chainage interval value
  draw_mode value // 1 to draw crosses at HIPs and VIPs, 0 don't draw
  spiral_type text
  hipdata { // some hips must exist and precede the VIP data
    x-value y-value radius // or
    x-value y-value radius spill left-spiral-length spil2 right-spiral-length
    " " " " " " " "
  }
  vipdata { // vips optional
    ch_value z-value parabolic-length // or
    ch_value z-value parabolic-length parabola // or
    ch_value z-value radius circle
    " " " "
  }
}
```

Arc String

```
string arc {
  model model_name  name string_name
  colour colour_name style style_name
  chainage start_chainage interval value radius value
  xcentre value ycentre value zcentre value
  xstart value ystart value zstart value
  xend value yend value zend value
}
```

Circle String

```
string circle {
  model model_name  name string_name
  colour colour_name style style_name
  chainage start_chainage interval value radius value
  zcentre value xcentre value ycentre value
}
```

Drainage String

```
string drainage {
  chainage start_chainage
  model model_name  name string_name
  colour colour_name style style_name
  breakline point or line
  attributes {
    text Tin finished_surface_tin
    text NSTin natural_surface_tin
    integer "_floating" 1/0 // 1 for floating, 0 not floating
  }
  outfall outfall_value // z-value at the outfall
  flow_direction 0/1 // 0 drainage line is defined from downstream
  // to upstream

  data { // key word - geometry of the drainage string
    x-value y-value z-value radius bulge
    " " "
    " " "
  }
  pit { // pit/manhole - one pit record for each pit/manhole
    // in the order along the string
    name text // pit name
    type text // pit type
    road_name text // road name
    road_chainage chainage // road chainage
    diameter value // pit diameter
    floating yes/no // is pit floating or not
    chainage pit_chainage // internal use only
    ip value // internal use only
    ratio value // internal use only
    x x-value // x-value of top of pit
    y y-value // y-value of top of pit
    z z-value // z-value of top of pit
  }
}
```

```

pipe {
    // one pipe record for each pipe connecting pits/manholes
    // in the order they occur along the string
    name          text          // pipe name
    type          text          // pipe type
    diameter      value         // pit diameter
    us_level      value         //
    ds_level      value         //
    us_hgl        value         //
    ds_hgl        value         //
    flow_velocity value         //
    flow_volume   value         //
}
property_control {
    name          text          // lot name
    colour        colour_name
    grade         value         // grade of pipe in units of "1v in"
    cover         value         // cover of the of pipe
    diameter      value         // diameter of the of pipe
    boundary      value         // boundary trap value
    chainage      chainage     // internal use only
    ip            value         // internal use only
    ratio         value         // internal use only
    x             x-value      // x value of where pipe connects to sewer
    y             y-value      // y value of where pipe connects to sewer
    z             z-value      // internal use only

    data {
        // key word - geometry of the property control
        x-value   y-value   z-value   radius   bulge
        "         "         "         "         "
        "         "         "         "         "
    }
}
house_connection { //warning - house connections may change in future versions
    name          text          // house connection name
    hcb           integer       // user given integer
    colour        colour_name
    grade         value         // grade of connection in units of "1v in"
    depth         value
    diameter      value
    side          left or right
    length        value
    type          text          // connection type
    material      text          // material type
    bush          text          // bush type
    level         value
    adopted_level value
    chainage      chainage     // internal use only
    ip            value         // internal use only
    ratio         value         // internal use only
    x             x-value      // x value of where pipe connects to sewer
    y             y-value      // y value of where pipe connects to sewer
    z             z-value      // internal use only
}
} // end of drainage-sewer data

```

Face String

```

string face {
  model model_name name string_name
  colour colour_name style style_name
  chainage start_chainage breakline point or line
  hatch_angle value
  hatch_distance value
  hatch_colour colour
  edge_colour colour
  fill_mode 0 or 1
  edge_mode 0 or 1
  data { // keyword
    x-value y-value z-value
    " " "
  }
}

```

Feature String

```

string feature {
  model model_name name string_name
  colour colour_name style style_name
  chainage start_chainage interval value radius value
  zcentre value xcentre value ycentre value
}

```

Interface String

```

string interface {
  chainage start_chainage
  model model_name name string_name
  colour colour_name style style_name
  breakline point or line
  data { // keyword
    x-value y-value z-value mode
    " " " " // mode = -1 cut
    " " " " //           0 surface
  } //           1 fill
}

```

Pipe String

```

string pipe {
  diameter value chainage start_chainage
  model model_name name string_name
  colour colour_name style style_name
  breakline point or line
  data { // keyword
    x-value y-value z-value
    " " "
    " " "
  }
}

```

Pipeline String

This is the same as an alignment string except that it has the additional keywords
 diameter, which gives the diameter of the pipeline in world units
 and
 length of the typical pipe making up the pipeline (used for deflections).

```
string pipeline {
  model model_name  name string_name
  colour colour_name  style style_name
  diameter diameter  length pipe-length
  chainage start_chainage  interval value
  spiral_type value
  hipdata {
    // some hips must exist and precede vips
    x-value  y-value  radius                                     // or
    x-value  y-value  radius  spill left-spiral-length  spil2  right-spiral-length
    "        "        "        "        "        "        "        "
  }
  vipdata {
    // vips optional
    ch-value  z-value  parabolic-length                                     // or
    ch-value  z-value  parabolic-length  parabola // or
    ch-value  z-value  radius  circle
    "        "        "        "
  }
}
```

Polyline String

The definition of a closed string has been refined for polyline and super strings. For other string types, closing a string simply meant having the first vertex the same as the last vertex. Hence the vertex was duplicated.

For a polyline string, being closed is a property of the string and no extra vertex is needed - the first and the last vertices are not the same and the polyline string knows there is an additional segment from the last vertex back to the first vertex.

In the 12d ascii format, there is a new *closed* flag for the polyline string:

```
closed  true  or  false
```

where *true* can be 1 or T or t or Y or y (or words starting with T, t, Y or y))
 and *false* is 0 or F or f or N or n (or words starting with F, f, N or n).

```
string polyline {
  chainage start_chainage
  model model_name  name string_name
  colour colour_name  style style_name
  breakline point or line
  closed true or false

  data {
    // keyword
    x-value  y-value  z-value  radius  bulge_flag
    "        "        "        "        "
    "        "        "        "        "
  }
}
```

Text String

```
string text {
```

```
x value y value z value
model model_name name string_name colour colour_name
text text_value
angle value offset value raise value
textstyle textstyle_name slant degrees xfactor value
worldsize value or papersize value or screensize value
justify "top/middle/bottom-left/centre/right"
}
```

Super String

Because the super string is so versatile, its 12d Ascii format looks complicated but it is very logical and actually quite simple.

In its most primitive form, the super string is simply a set of (x,y) values as in a 2d string, or (x,y,z) values as in a 3d string, or (x,y,z,radius,bulge_flag) as for a polyline string or even lines, arcs and transition spirals.

Additional blocks of information can extend the definition of the super string. For example, text, pipe diameters and visibility.

Some of the properties of the super string extend what were constant properties for the entire string in other string types. For example, *breakline* type for the string extends to *tinability* of *vertices* and *segments*. One colour for the string extends to individual colours for each segment.

Other properties such as vertex id's (point numbers), visibility and culvert data are entirely new.

For user attributes, the super string still has the standard user attributes defined for the entire string, but user attributes for each vertex and segment are also supported.

The definition of a closed string has been refined for polyline and super strings. For other string types, closing a string simply meant having the first vertex the same as the last vertex. Hence the vertex was duplicated.

For a super string, being closed is a property of the string and no extra vertex is needed. That is, the first and the last vertices are not the same for a closed super string and the super string knows there is an additional segment from the last vertex back to the first vertex.

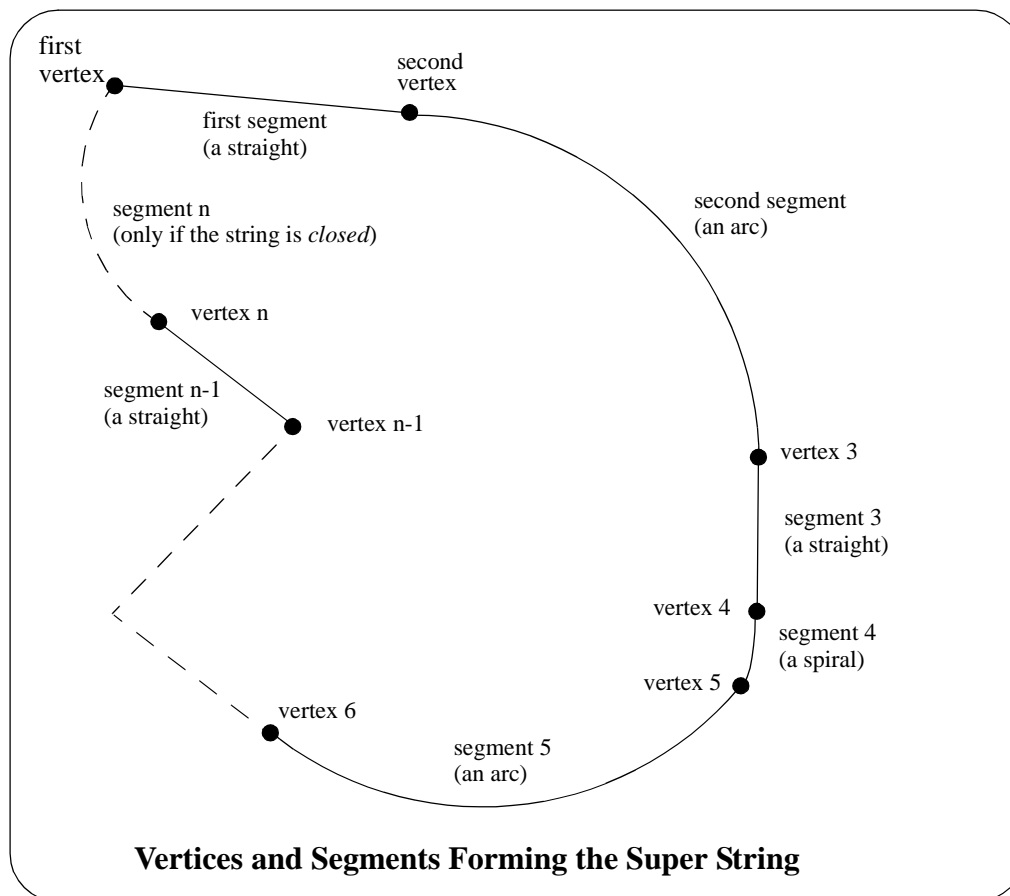

Hence in the 12d ascii format, there is a *closed* flag for the super string:

closed *true* or *false*

where *true* can be 1 or T or t or Y or y (or words starting with T, t, Y or y)) and *false* is 0 or F or f or N or n (or words starting with F, f, N or n).

Thus if a string has n vertices, then an open string has $n-1$ segments joining the vertices and a closed string has n segments since there is an additional segment from the last to the first vertex.

With the additional data for vertices and segments in the super string, the data is in vertex or segment order. So for a string with n vertices, there must be n bits of vertex data. For segments, if the string is open then there only needs to be $n-1$ bits of segment data but for closed strings, there must be n bits of data. For an open string, n bits of segment data can be specified and the n th bit will be read in and stored. If the string is then closed, the n th bit of data will be used for the extra segment.

The full 12d Ascii definition of the super string is:

```
string super {
  chainage start_chainage
  model model_name name string_name
  colour colour_name style style_name
  breakline point or line
  closed true or false
  interval {
    chord_arc value // chord-to-arc tolerance for curves
    distance value // chainage interval to break the geometry up
  }

  block of info {
  }
  block of info {
  }
  block of info {
  }
}
```

The blocks of info can be broken up into four types.

- (a) blocks defining the position of the vertices in x, y and z
data_2d or *data_3d*

- (b) blocks defining the geometry of the segments
radius_data and *major_data* or *geometry_data*
- (c) a superseded block defining vertices and segment geometry
data
- (d) extra information for the vertices and/or segments
 pipe diameters - *diameter_value* or *diameter_data*
 culvert dimensions - *culvert_value* or *culvert_data*
 pipe/culvert justification - *justify*
 colour - *colour* or *colour_data*
 vertex ids (point numbers) at each vertex- *point_data*
 tinability - *breakline* or *vertex_tinability_data* and *segment_tinability_data*
 visibility - *vertex_visible_data* and *segment_visible_data*
 vertex text and annotation - *vertex_text_data* and *vertex_annotation_data*
 segment text and annotation - *segment_text_data* and *segment_annotation_data*
 symbols at vertices - *symbol_value* or *symbol_data*
 vertex attributes - *vertex_attribute_data*
 segment attributes - *segment_attribute_data*
 extrudes
 image data
 holes

The definition for the blocks of each type now follows.

(a) Blocks Defining the Position of the Vertices

For (x, y) Values with a Constant z

If there is only (x,y) values at each vertex (like a 2d string):

```
data_2d { // keyword
    x-value  y-value
    "        "
    "        "
}
```

and if there is a non-null constant z for the string

```
z  value
```

For (x, y,z) Values

If there is (x,y,z) values at each vertex (like a 3d string):

```
data_3d { // keyword
    x-value  y-value  z-value
    "        "        "
    "        "        "
}
```

(b) Blocks Defining the Geometry of the Segments

Straights and Arcs Only for the Segments

If *data_2d* or *data_3d* was used, it is possible to add *radius* and *bulge_flag* data:

```
radius_data { // keyword
    radius for first segment
    radius for second segment
```

```

        ...
        radius for last segment
    }

major_data {                                     // keyword
    bulge flag for first segment
    bulge flag for second segment
    ...
    bulge flag for last segment
}

```

Straights, Arcs and Transitions for the Segments

If `data_2d` or `data_3d` was used, it is possible to specify if the segments are straight, arcs or spirals using a `geometry_data` block.

```

geometry_data {
    segment_info_1 {
        information on the first segment
    }
    segment_info_2 {
        information on the second segment
    }
    " "
    " "
    segment_info_n-1 {           // the last segment if it is open
        information on the (n-1) segment
    }
    segment_info_n {           // the last segment if it is closed
        information on the n-th segment
    }
}

```

where the `segment_info` blocks are from the following:

(a) Straight

No parameters are needed for defining a straight segment. The `straight` block is simply:

```

straight {                                     // no parameters are needed for a straight
}

```

(b) Arc

There are four possibilities for an arc of a given radius placed between two vertices.

We use *positive* and *negative* radius, and a flag *major* which can be set to 1 (on) or off (0) to differentiate between the four possibilities.

So the `arc` block is:

```

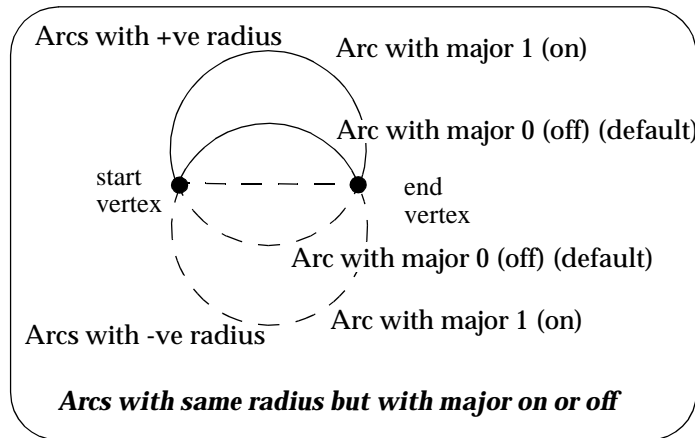

arc {
    radius value // radius of the arc (+ve is above the line connecting the vertices)
    major 0 or 1 // 0 is the smaller arc, 1 the larger arc).
}

```

(c) Spiral

There can be a partial spiral between adjacent vertices. The partial spiral is defined by the parameters

l1 length of the full spiral up to the start vertex

- r1 radius at the start vertex
- a1 angle in decimal degrees of the tangent to the spiral at the start vertex
- l2 length of the full spiral up to the end vertex
- r2 radius at the end vertex
- a2 angle in decimal degrees of the tangent to the spiral at the end vertex

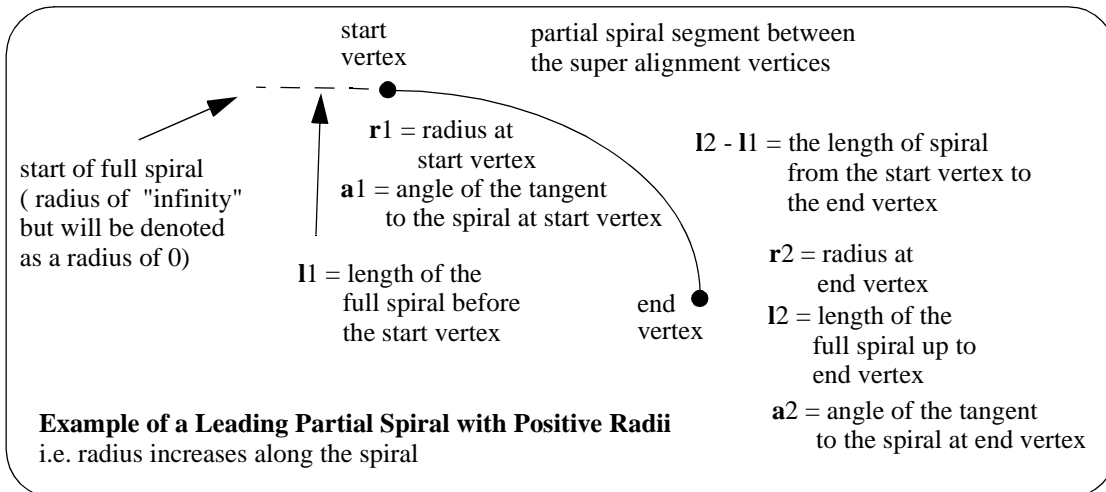

Since a radius can not be zero, a radius of infinity is denoted by *zero*.

The spiral is said to be a *leading* spiral if the absolute value of the radius is increasing along the direction of the spiral (the spiral will *tighten*). Otherwise it is a *trailing* spiral.

If a leading spiral is a full spiral then $r1 = 0$ and $l1 = 0$. Similarly if a trailing spiral is a full spiral then $r2 = 0$ and $l2 = 0$.

For a partial spiral, if the coordinates of the start of the full spiral are needed then they can be calculated from $l1, r1, a1, l2, r2, a2$ and the co-ordinates of the start and end vertices.

Note that the radii can be positive or negative. If the radii's are positive then a leading spiral will curl to the right (and will be above the line joining the start and end vertices).

The parameters for the *spiral* block are:

```

spiral {
  type      value           // any of the spirals supported in spirals.4d
  leading   1 or 0         // 1 denotes a leading spiral, 0 a trailing spiral
  l1        value         // length of the full spiral at start vertex
  r1        value         // radius at the start vertex
  a1        value         // angle in decimal degrees of the tangent to the spiral
                          // at the start vertex

```

```

l2      value           // length of the full spiral at end vertex
r2      value           // radius at end vertex
a2      value           // angle in decimal degrees of the tangent to the spiral
                        // at the end vertex
}

```

(c) Block Defining the Vertices and Segments

For compatibility with the polyline, the *data* block gives the (x,y,z,radius,bulge) values at each vertex of the string and so defines both the vertices and the geometry of the segments in the one block.

```

data {
    x-value  y-value  z-value  radius  bulge           // keyword
    "        "        "        "        "
    "        "        "        "        "
}

```

(d) Other Blocks

Pipe Diameters

There can be one pipe diameter value for the entire super string or the pipe diameter varies for each segment of the super string.

```

diameter_value value
or
diameter_data {
    pipe diameter for first segment           // keyword
    pipe diameter for second segment
    ...
    pipe diameter for last segment
}

```

Culvert Dimensions

There can be one culvert width and height for the entire super string or the culvert width and height vary for each segment of the super string.

```

culvert_value { width  value
                height value
                }
or
culvert_data { properties {width  value           // width and height for first segment
                          height value
                          }
               properties {width  value           // width and height for second segment
                          height value
                          }
               ...
               }
               properties {width  value           // width and height for last segment
                          height value
                          }
               }
}

```

Justification for Pipe or Culverts

There can be only one justification for the pipe or culvert for the entire super string.

```
justify justification           // "bottom" or "invert"
                               // "top" or "obvert"
                               // "centre" (default)
```

Colour

There can be one colour for the entire super string which is given by the `colour` command at the beginning of the string definitions (before the blocks of information) or the colour varies for each segment of the super string and is specified in a `colour_data` block.

```
colour_data {                               // keyword
    colour for first segment
    colour for second segment
    ...
    colour for last segment
}
```

Vertex Id's (Point Numbers)

Each vertex can have a vertex id (point number). This is not the order number of the vertex in the string but is a separate id which is usually different for every vertex in every string. The vertex id can be alphanumeric.

```
point_data {                               // keyword
    vertex id or first vertex              // alphanumeric
    vertex id for second vertex
    ...
    vertex id for last vertex
}
```

Tinability

For a *super string*, the concept of breakline has been extended to a property called **tinable** which can be set independently for each vertex and each segment of the super string.

If a vertex is tinable, then the vertex is used in triangulations. If the vertex is not tinable, then the vertex is ignored when triangulating.

If a segment is tinable, then the segment is used as a side of a triangle during triangulation. This may not be possible if there are *crossing* tinable segments.

```
vertex_tinable_data {                     // keyword
    tinable flag for first vertex          // 1 for tinable
    tinable flag for second vertex        // 0 for not tinable
    ...
    tinable flag for last vertex
}

segment_tinable_data {                   // keyword
    tinable flag for first segment         // 1 for tinable
    tinable flag for second segment       // 0 for not tinable
    ...
    tinable flag for last segment
}
```

Note that even if a segment is set to tinable, it can only be used if both its end vertices are also

tinable.

Visibility

For a *super string*, the concept of visibility and invisibility for vertices and segments has been introduced.

```

vertex_visible_data {
    visibility flag for first vertex // keyword // 1 for visible
    visibility flag for second vertex // 0 for invisible
    ...
    visibility flag for last vertex
}

segment_visible_data {
    visibility flag for first segment // keyword // 1 for visible
    visibility flag for second segment // 0 for invisible
    ...
    visibility flag for last segment
}

```

Vertex Text and Vertex Annotation

There can be the same piece of text for every vertex in the super string or a different text for each vertex of the super string. How the text is drawn is specified by vertex annotation values. Note that in vertex annotations, all vertices must be either worldsize or all vertices papersize. That is, worldsize and papersize can not be mixed - the first one found is used for all vertices.

```

vertex_text_value      text
or
vertex_text_data {
    text for first vertex // keyword // text string, enclose
    text for second vertex // by "" if there are any
    ... // spaces in the text string
    text for last vertex
}

vertex_annotate_value {
    angle value offset value raise value // keyword
    textstyle textstyle_name slant degrees xfactor value
    worldsize value or papersize value or screensize value
    justify "top/middle/bottom-left/centre/right"
    colour colour_name
}
or
vertex_annotate_data {
    properties { // keyword
        angle value offset value raise value
        textstyle textstyle slant degrees xfactor value
        worldsize value or papersize value or screensize value
        justify "top/middle/bottom-left/centre/right"
        colour colour_name
    }
    properties { text properties second vertex
    }
    properties { ...
    }
    properties { text properties for last vertex
    }
}

```

Segment Text and Segment Annotation

There can be the same piece of text for every segment in the super string or a different text for each segment of the super string. How the text is drawn is specified by segment annotation values. Note that in segment annotations, all segments must be either worldsize or all segments papersize. That is, worldsize and papersize can not be mixed - the first one found is used for all segments. However, vertex text and segment text do not both have to be papersize or worldsize.

```

segment_text_value      text
or
segment_text_data {
    text for first segment           // keyword
    text for second segment         // text string, enclose
    ...                             // by "" if there are any
    text for last segment           // spaces in the text string
}

segment_annotate_value {
    angle value offset value raise value // keyword
    textstyle textstyle slant degrees xfactor value
    worldsize value or papersize value or screensize value
    justify "top/middle/bottom-left/centre/right"
    colour colour_name
}
or
segment_annotate_data {
    properties { angle value offset value raise value // keyword
                textstyle textstyle slant degrees xfactor value
                worldsize value or papersize value or screensize value
                justify "top/middle/bottom-left/centre/right"
                colour colour_name
            }
    properties { text properties second segment
            }
    properties { ...
            }
    properties { text properties for last segment
            }
}

```

Symbols

There can be the same symbol (defined as a linestyle) for every vertex in the super string or a different symbol for each vertex of the super string. If a symbol does not have a colour, then it uses the string colour or the segment colour.

```

symbol_value {
    style linestyle_name colour colour_name size value // keyword
    rotation value // in dms
    offset value raise value
}
or
symbol_data {
    properties { style linestyle_name colour colour_name size value // keyword
            style linestyle colour colour size value
    }
}

```

```

        rotation value // in dms
        offset value raise value
    }
    properties { symbol and properties for second vertex
    }
    properties { ...
    }
    properties { symbol and properties for last vertex
    }
}

```

Vertex Attributes

Each vertex can have one or more user defined named attributes.

```

vertex_attribute_data { // key word
    attributes { attribute_type attribute_name attribute_value
                attribute_type attribute_name attribute_value
                ...
                attribute_type attribute_name attribute_value
    }
    attributes { named attributes for second vertex
    }
    attributes { ...
    }
    attributes { named attributes for last vertex
    }
}

```

Segment Attributes

Each segment can have one or more user defined named attributes.

```

segment_attribute_data { // keyword
    attributes { attribute_type attribute_name attribute_value
                attribute_type attribute_name attribute_value
                ...
                attribute_type attribute_name attribute_value
    }
    attributes { named attributes for second segment
    }
    attributes { ...
    }
    attributes { named attributes for last segment
    }
}

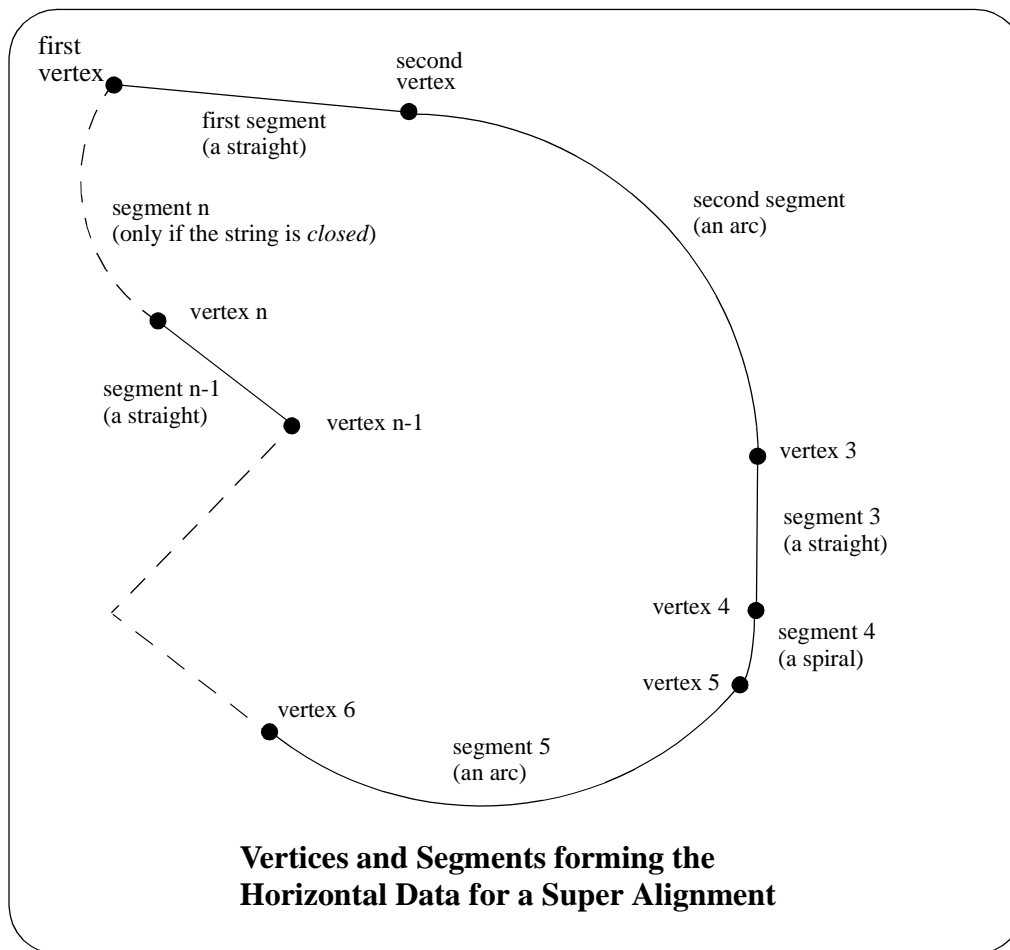

```

Super Alignment String

In an alignment string, the horizontal and vertical geometry are defined separately and only the intersection point method (IP's) could be used. The IP definition is actually a *constructive* definition and the tangents points and segments between the tangent points (lines, arcs etc.) are calculated from the IP definition. For an alignment string, only the IP definitions was included in the 12d ascii file, not the calculated segments.

For a super alignment, the horizontal and vertical geometry are also defined separately and with construction definitions but the construction definition can be much more complex than just IP's.

Unlike the alignment, the super alignment stores **both** the **constructive methods** (*parts*) and the resulting **vertices** and **segments** (lines, arcs, transitions etc.) that make up the horizontal and vertical geometry.

For many applications such as uploading to survey data collectors or machine control devices, only the horizontal data and the vertical data are required, not the *constructive* information.

Note that segments meeting at a common vertex do not have to be tangential although for most road applications, they should be.

The full 12d Ascii definition of the *super alignment* is:

```

string super_alignment {
//
    name            string_name
    chainage        start_chainage
    colour          colour_name
    style           style_name
    breakline       point or line
    closed          true or false
    spiral_type     transition_type           // currently only "Clothoid"
    valid_horizontal true or false
    valid_vertical  true or false

    block of info {
    }
    block of info {
    }
    block of info {
    }
}
// end of super alignment

```

where the block of info can be one of more of:

attributes, horizontal_parts, horizontal_data, vertical_parts, vertical_data.

The **attributes** block has been described in the earlier section “Attributes” .

The structure of the blocks *horizontal_parts*, *horizontal_data*, *vertical_parts* and *vertical_data* will now be described in more detail.

Horizontal Geometry

The horizontal geometry is described by two blocks - the **horizontal_parts** block and the *horizontal_data* block. The *horizontal_parts* block contains the **methods** to construct the horizontal geometry such as float (fillet) an arc of a certain radius between two given lines or create a transition spiral between a line and an arc.

If the horizontal construction methods are consistent, then they can be solved to form a string made up of lines, arcs and transitions. The *horizontal_data* block is simply a list of the vertices and segments (lines, arcs etc.) that make up the *solved* geometry.

If the geometry in the *horizontal_parts* can be solved and produces a valid *horizontal_data* block, then a flag *valid_horizontal* is set to *true*.

```

valid_horizontal true or false //true if the horizontal geometry can be solved and
// hence create a valid horizontal_data
horizontal_parts {/           / methods for creating the horizontal geometry
    ....
}
horizontal_data {           // the horizontal geometry
    ....
}

```

Horizontal_parts

The *horizontal_parts* block describes the methods used to construct the horizontal geometry of the

super alignment. Unless another software package supports all the construction methods allowed in 12d Model, this block should be skipped.

The *horizontal_parts* block is undocumented.

Horizontal_data

The *horizontal_data* block contains the *solved* horizontal geometry of the super alignment.

The *solved horizontal geometry* is made up of a series of (x,y) vertices given in a *data_2d* block followed by a *geometry_data* block specifying the geometry of the segments between adjacent vertices. The segment can be a straight line, an arc or a transition (e.g. spiral).

If the horizontal geometry has n vertices, then there will be (n-1) segments for an *open* super alignment or n segments if the super alignment is *closed*.

The format of the *horizontal_data* block is:

```
horizontal_data {
  name          " "
  chainage      value
  breakline     line or point
  colour        colour
  style         linestyle
  closed        0 or 1           // 0 if the string is open, 1 if it is closed

  interval {
    chord_arc   value           // chord-to-arc tolerance for curves
    distance    value           // chainage interval to break the geometry up
  }

  data_2d {
    x1-value    y1-value        // co-ordinates of the first vertex
    x2-value    y2-value        // co-ordinates of the second vertex
    "           "
    "           "
    xn-value    yn-value        // co-ordinates of the n-th vertex
  }

  geometry_data {
    segment_info_1 {
      information on the first segment
    }
    segment_info_2 {
      information on the second segment
    }
    "           "
    "           "
    segment_info_n-1 {           // the last segment if it is open
      information on the (n-1) segment
    }
    segment_info_n {           // the last segment if it is closed
      information on the n-th segment
    }
  }
}
```

where the *segment_info* blocks are from the following:

(a) Straight

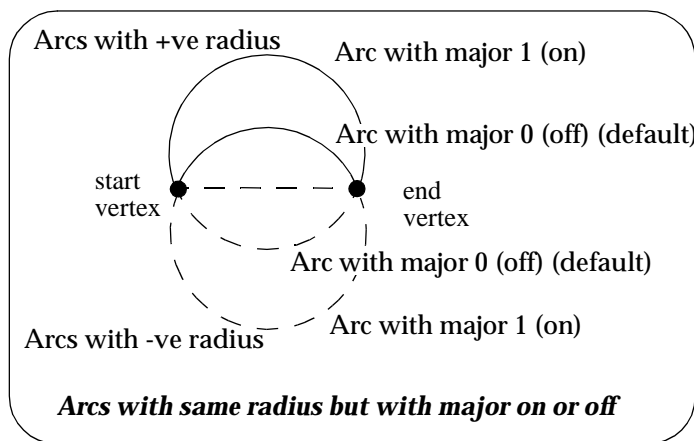

No parameters are needed for defining a straight segment. The *straight* block is simply:

```
straight {           // no parameters are needed for a straight
}
}
```

(b) Arc

There are four possibilities for an arc of a given radius placed between two vertices.

We use *positive* and *negative* radius, and a flag *major* which can be set to 1 (on) or off (0) to differentiate between the four possibilities.

So the *arc* block is:

```
arc {
  radius value // radius of the arc (+ve is above the line connecting the vertices)
  major 0 or 1 // 0 is the smaller arc, 1 the larger arc).
}
```

(c) Spiral

There can be a partial spiral between adjacent vertices. The partial spiral is defined by the parameters

- l1** length of the full spiral up to the start vertex
- r1** radius at the start vertex
- a1** angle in decimal degrees of the tangent to the spiral at the start vertex
- l2** length of the full spiral up to the end vertex
- r2** radius at the end vertex
- a2** angle in decimal degrees of the tangent to the spiral at the end vertex

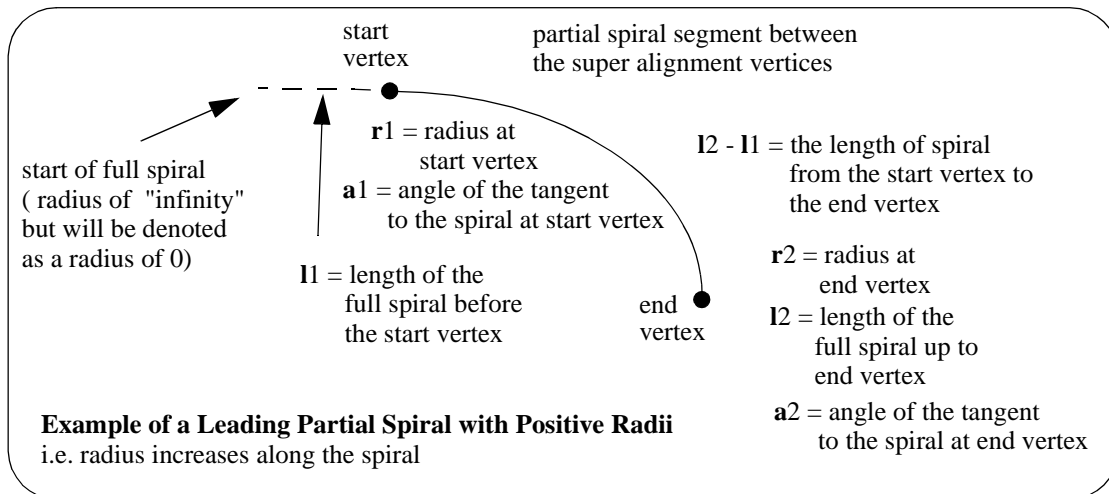

Since a radius can not be zero, a radius of infinity is denoted by *zero*.

The spiral is said to be a *leading* spiral if the absolute value of the radius is increasing along the direction of the spiral (the spiral will *tighten*). Otherwise it is a *trailing* spiral.

If a leading spiral is a full spiral then $r1 = 0$ and $l1 = 0$. Similarly if a trailing spiral is a full spiral then $r2 = 0$ and $l2 = 0$.

For a partial spiral, if the coordinates of the start of the full spiral are needed then they can be calculated from $l1, r1, a1, l2, r2, a2$ and the co-ordinates of the start and end vertices.

Note that the radii can be positive or negative. If the radii's are positive then a leading spiral will curl to the right (and will be above the line joining the start and end vertices).

The super alignment currently only supports a transition type of *clothoid spiral*, but in future releases more transition types will be supported.

The parameters for the *spiral* block are:

```

spiral {
  type      "clothoid"           // only clothoid is currently supported
  leading   1 or 0              // 1 denotes a leading spiral, 0 a trailing spiral
  l1        value               // length of the full spiral at start vertex
  r1        value               // radius at the start vertex
  a1        value               // angle in decimal degrees of the tangent to the spiral
                                   // at the start vertex
  l2        value               // length of the full spiral at end vertex
  r2        value               // radius at end vertex
  a2        value               // angle in decimal degrees of the tangent to the spiral
                                   // at the end vertex
}

```

Vertical Geometry

The *vertical* geometry is described by two blocks - the *vertical_parts* block and the *vertical_data* block. The *vertical_parts* block contains the **methods** to construct the vertical geometry such as float (fit) a parabola of a certain length between two given lines.

If the vertical construction methods are consistent, then they can be solved to form a string made up of lines, parabolas and arcs. The *vertical_data* block is simply a list of the vertices and segments (lines, parabolas and arcs) that make up the *solved* geometry.

If the geometry in the *vertical_parts* can be solved and produces a valid *vertical_data* block, then a flag *valid_vertical* is set to *true*.

```

valid_vertical  true or false // true if the vertical geometry can be solved and
                                   // hence create a valid vertical_data
vertical_parts {                    // methods for creating the vertical geometry
  ....
}
vertical_data {                      // the vertical geometry
  ....
}

```

Vertical_parts

The *vertical_parts* block describes the methods used to construct the vertical geometry of the super alignment. Unless another software package supports all the construction methods allowed in 12d Model, this block should be skipped.

The *vertical_parts* block is undocumented.

Vertical_data

The *vertical_data* block contains the *solved* vertical geometry of the super alignment.

The *solved vertical geometry* is made up of a series of (chainage,height) vertices given in a *data_2d* block followed by a *geometry_data* block specifying the geometry of the segments between adjacent vertices. The segment can be a straight line, a parabola or an arc.

If the vertical geometry has n vertices, then there will be (n-1) segments for an *open* super alignment or n segments if the super alignment is *closed*.

The format of the *vertical_data* block is:

```
vertical_data {
  name      ""
  chainage  value
  breakline line or point
  colour    colour
  style     linestyle
  closed    0 or 1           // 0 if the string is open, 1 if it is closed
  interval {
    chord_arc  value           // chord-to-arc tolerance for curves
    distance   value           // chainage interval to break the geometry up
  }

  data_2d {
    ch1-value  ht1-value       // co-ordinates of the first vertex
    ch2-value  ht2-value       // co-ordinates of the second vertex
    "          "
    "          "
    chn-value  htn-value       // co-ordinates of the n-th vertex
  }

  geometry_data {
    segment_info_1 {
      information on the first segment
    }
    segment_info_2 {
      information on the second segment
    }
    "          "
    "          "
    segment_info_n-1 {           // the last segment if it is open
      information on the (n-1) segment
    }
    segment_info_n {           // the last segment if it is closed
      information on the n-th segment
    }
  }
}
```

where the *segment_info* blocks are from the following:

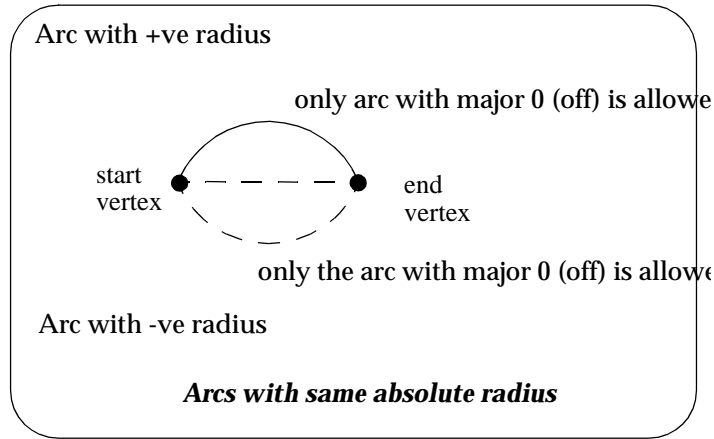

(a) Straight

No parameters are needed for defining a straight segment. The *straight* block is simply:

```
straight {           // no parameters are needed for a straight
}
}
```

(b) Arc

Since vertical geometry can't go backwards in chainage value, the majors arcs can not be used and hence there are only possibilities for an arc of a given radius placed between two vertices. We use *positive* and *negative* radius to differentiate between the four possibilities.

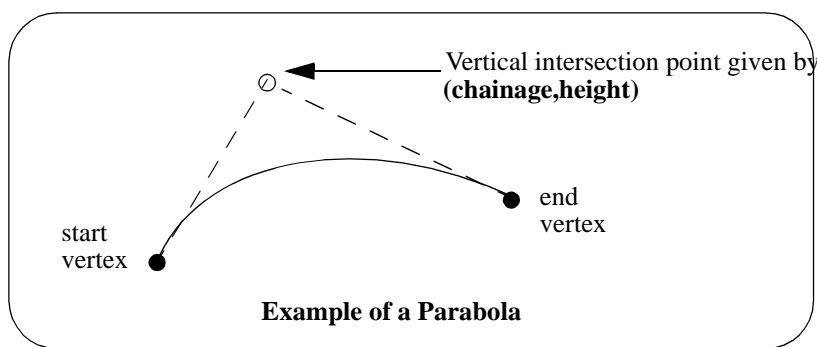

So the *arc* block is:

```
arc {
  radius value // radius of the arc (+ve is above the line connecting vertices)
  major value // this is ignored since only minor arcs are used
}
```

(c) Parabola

There can be a parabola between adjacent vertices. The parabola is defined by giving the coordinates of the vertical intersection point for the parabola

chainage chainage of the VIP of the parabola
height height of the VIP of the parabola

The parameters for the *parabola* block are:

```
parabola {
  chainage value // chainage of the VIP of the parabola
  height value // height of the VIP of the parabola
}
```

Please continue to the next section "12d Ascii Definition for Tins"

12d Ascii Definition for Tins

Tins (triangulated irregular networks) and *Super Tins* can be written out and read in from a 12d Ascii file.

Tins

```

tin {
  name  tin_name      // MANDATORY name of the tin when created in 12d Model

  time_created text           // optional - time tin first created
  time_updated text          // optional - time tin last modified

  // Attributes Block:

  // This is mainly information used by 12d Model to create the tin.
  // The attributes this block and the Attributes block itself are optional.
  // When a tin is read into 12d Model from a 12da file, the style is used
  // as the Tin style.

  attributes {
    text "style"          text           // name of line style for the tin
    integer "faces"       0/1           // 0 non triangle data, 1 triangle data
    real "null_length"    value          // values for null by angle/length
    real "null_angle"     value          // angle in radians
    real "null_combined_length" value     // angle in radians
    real "null_combined_angle" value     // angle in radians
  //      any other attributes
  }
  // end of attributes block

  // Points Block
  //
  // Co-ordinates of the points at the vertices of the triangles
  // The points are implicitly numbered by the order in the list (starting at point 1).
  //
  // The Points Block is MANDATORY

  points {
    x-value y-value z-value // x y z for each point in the tin
    " " " " " // point 1
    " " " " " // point 2
  }
  // end of points block

  // Triangles Block
  //
  // Each triangle is given as a triplet of the point numbers that make up
  // the triangle vertices (the point numbers are the implicit position of the points
  // given in the Points Block.
  // The order of the triangles is unimportant
  //
  // The Triangles Block is MANDATORY

```

```

triangles {
    T1-1  T1-2  T1-3      // points making up each triangle
    T2-1  T2-2  T-33     // point numbers of the 3 vertices of first triangle.
    "      "           // point numbers of the 3 vertices of second triangle.
    "      "           "
} // end of triangles block

// Base Colour
// The tin has a base colour that is the default colour for all triangles

colour tin_base_colour // optional - base colour of the tin

// Colours Block
//
// Triangles can be given colours other than the base colour by including
// a "colours" block. The colour for each triangle is then individually given
// (-1 means base colour). The order is the same as the order of the triangles in
// the Triangles Block.
//
// If all the triangles are the base colour, then simply omit the Colours Block

colours {
    C1  C2  C3          // colour for each triangle given in triangle order
    C4  C5  C6  C7     // colour "-1" means use the base tin colour.
    "   "   "
    "   "   "
} // end of colours block

// Input Block
//
// More information about how the tin was created by 12d Model.
// None of this information is needed when reading a tin into 12d Model.
// This block can be omitted

input {
    preserve_strings  true/false // data for reconstructing tin from strings
    remove_bubbles   true/false // if true, preserve breaklines etc.
    weed_tin         true/false //
    triangle_data    true/false
    sort_tin         true/false
    cell_method      true/false

    models {
        "model_name_1" // name of the first model making up the tin
        "model_name_2" // name of the second model making up the tin
        "  "  "  "
        "  "  "  "
    } // end of models block
} // end of input block
} // end of tin ascii definition

```

Super Tins

```

super_tin {
    name tin_name // MANDATORY name of the super tin

    time_created text // optional - time super tin first created
    time_updated text // optional - time super tin last modified

// Attributes Block:

// This is mainly information used by 12d Model to create the super tin.
// The attributes in this block and the Attributes block itself are optional.
// When a super tin is read into 12d Model from a 12da file, the style is used
// as the Super Tin style.

    attributes {
        text "style" text // name of line style for the tin
// any other attributes
    } // end of attributes block

// Super Tin Colour
// The super tin has a base colour

    colour tin_base_colour // optional - base colour of the super tin

// Tins Block
//
// This is the list of tins that make up the super tin.
// This block is MANDATORY

    tins { // list of tins for the super tin
        "tin_name_1" // name of the first tin making up the super tin
        "tin_name_2" // name of the second tin making up the super tin
        " " " "
        " " " "
    } // end of tins block
} // end of super tin ascii definition

```

Please continue to the next section “12d Ascii Definition for Plot Frames” .

12d Ascii Definition for Plot Frames

Plot frames can be written out and read in from a 12d Ascii file.

```
string plot_frame {  
  name           frame_name  
  title_file     filename  
  border         0 or 1  
  viewport       0 or 1  
  user_title_file 0 or 1  
  title_1        text  
  title_2        text  
  plot_file      filename  
  text_size      mm  
  sheet_code     text  
  width          value  
  height         value  
  scale          value  
  rotation       value  
  xorigin        value  
  yorigin        value  
  left_margin    mm  
  right_margin   mm  
  top_margin     mm  
  bottom_margin  mm  
  plotter        text  
  colour         colour  
  textstyle      textstyle_name  
}
```

J Set Ups

Set Up Files

When 12d Model fires up, it looks for special files (called set up files) to define many of its features. Hence the set up files can be used to customize 12d Model for a site or a user.

Two set up files, **setups.4d** and **defaults.4d**, are only used when creating a new project. After the project is created, the information supplied in the two set up files is stored with the project and is then modified from within the project.

Similarly the file **macros.4d** is a file of macros (one per line) that are run when a new project is created.

defaults.4d // define the defaults for a **new** project
(**Defaults** panel from the **Utilities =>Defaults** option).
Once a project is created, the defaults can be modified inside 12d Model.
The defaults are then saved with the project.

For more information go to the section “Defaults”

setups.4d // define the layout of views on the screen for a **new** project. Once a project is created, the view layout can be modified inside 12d Model. The view layout is then saved with the project.

For more information go to the section “Set Ups”

macros.4d // a file of macros (one per line) that are run when a **new** project is created.

The other set up files are searched for each time a project is opened and hence can be modified between access to the project. The complete list of set up files that 12d Model searches for each time a project is opened is:

colours.4d // sets the colour names and red, green, blue mix; also defines the default pens that the colours map to (as displayed in the panel **colours to pens**). See “Colours” .

digitize.4d // list and defines the digitizers available in 12d Model. See “Digitizer Definitions File” .

env.4d // contains values for environment variables See “Environment Variables” .

fonts.4d // defines the fonts used in text styles. See “Textstyles and Fonts” .

gui.4d // define the fonts and colours used in panels and menus, spacing between items in panels and menus and the maximum pop-up length. See “GUI” .

layout.4d // a screen layout file that is used every time a project is opened. A screen layout file can have most menus and panels in it. See “Screen Layout File” in the appendix “Special File Formats” .

linestyl.4d // defines the line styles (linestyles, worldstyles, groupstyles and twoptstyles). See “Line Styles” .

names.4d // a special mapping file which is used to fill out information such as colours, model etc. for given string names.

plotters.4d // defines the plotters that appear in the pop-up for the plotter type panel field. See “User Defined Plotters” .

pmf.4d // plotter mapping file for defining mapping of 12d Model colours to pens with thicknesses, and the rgb for the pens See “Plotter Mapping File”

sheets.4d // gives sheet sizes and names used in the pop-up for the sheet size panel field. See “Sheet Sizes”

spirals.4d // defines the transition curves (spirals). See "Spirals" .
survey.4d // lists and defines the data collectors available in 12d Model See "Survey Data Collectors"
symbols.4d // defines the symbols. See "Symbols"
textstyl.4d // defines the text styles. See "Textstyles and Fonts" .
textstyle_names.4d // defines the textstyle favourites
toolbars.4d // defines the toolbars See "User Defined Toolbars"
userkeys.4d // defines the action of function keys. See "User Defined Function Keys"
usermenu.4d // defines the user defined walk-right menus for User on 12d Model menus. See "User Defined Menus" .
xtramenu.4d // defines the 12D Solutions defined walk-right menus for User on 12d Model menus. See "User Defined Menus" .

When 12d Model creates a new project, or changes to another project, it searches for set up files in a number of set folders. For each file, these folders are searched in a specific order until the file is found. Consequently the set up files do not all have to be in the same folder.

This greatly increase the tailorability of 12d Model.

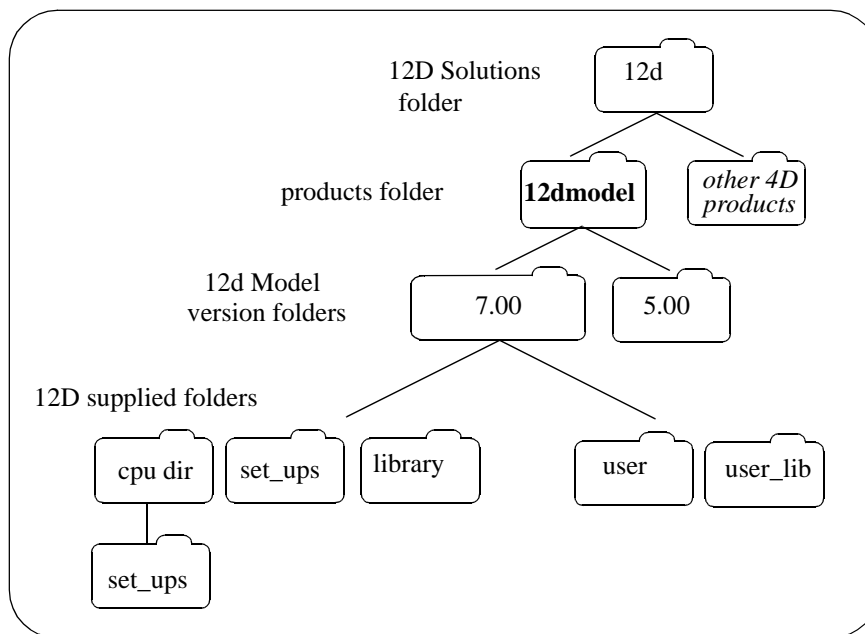

For set up files, the folders searched and their search order will now be described in the next section "Folders Searched for Set Up Files" .

Folders Searched for Set Up Files

Set_Ups

When 12d Model V7.0 is installed on a computer, it is placed in a folder called **7.00** in the folder **12d\12dmodel**.

The 12d Model installation creates a number of specific folders such as the operating system-cpu specific folder (for example **nt.x86** for Windows NT on Intel chips), and areas for set up files: namely an o/s-cpu specific **set_ups** under the o/s-specific folder and a **set_ups** under **7.00**.

User

Although users can place their site specific set up files in the **set_ups** folders, it is not recommend since they may be overwritten during future 12d Model installations.

To overcome this problem, there is a special folder (reserved for customers) called **user** which is searched **before set_ups** for any set up files. Consequently any site specific set up files should be placed in **user** and they will be used in preference to the files in **set_ups** (**user** may contain o/s-cpu specific folders). By default, **user** is under **7.00**.

When a new 12d Model version is issued (e.g. V7.0), **user** can then be copied over to the new installation area.

There is also an environment variable which can be set to point to another user defined folder which will be searched for set up files before the default **user** is searched.

```
USER_4D          folder      // users own folder for set up info
```

Note - both **user** and the folder pointed to by **USER_4D** can exist.

Current and Home

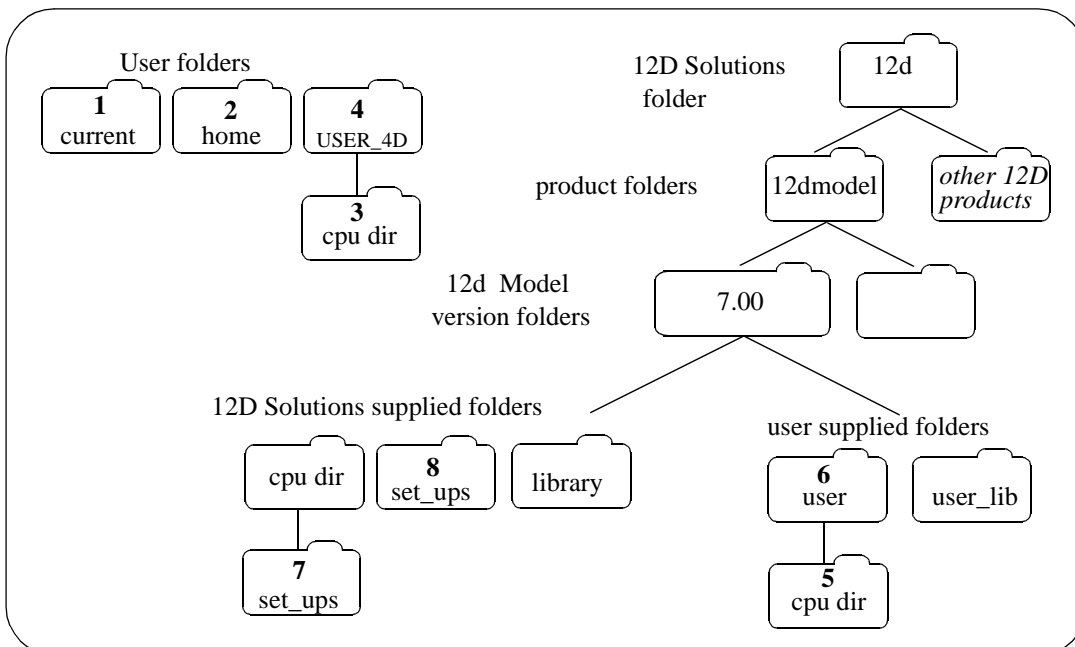

The folder that a project is in (the **current** folder) and the users **home** folder are also searched for set up files.

Searching Order for Set Up Files

When 12d Model creates a new project, or changes to another project, it searches for set up files in a number of set folders. For each file, these folders are searched in a specific order until the file is found. Consequently the set up files do not all have to be in the same folder.

The folder search order for the set up files is

0. the appropriate environment variable defining where the file is
1. the projects current folder
2. the users home folder
3. specific cpu folder in USER_4D e.g. nt.x86 for Intel
4. USER_4D
5. specific cpu folder in user
6. user
7. SET_UPS_4D
8. set_ups folder under the specific cpu folder in 7.00
9. set_ups folder under 7.00

Notes

- (a) When an **existing** project is opened by 12d Model, the set up files setups.4d and defaults.4d are not used.
- (b) The file, **eagleplt.emf**, is not pointed to by an environment variable but is searched for.

Writing Set Up Files

Most of the set up files can be created and edited totally within 12d Model using panels such as **Defaults** which is accessed via the *Utilities =>Defaults* option.

When the **Write** button is selected on the panels, a **Write Setup File** panel comes up to specify where the file is to be written out to.

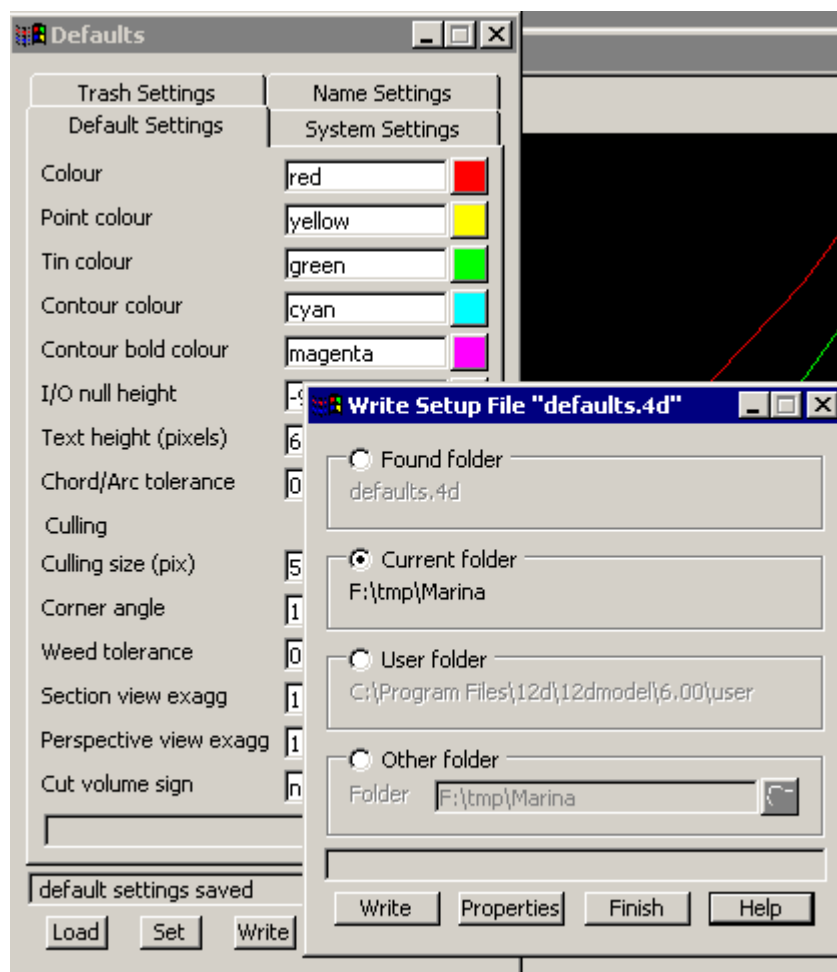

The choices on the panel allow the file to be written out to:

Found folder - the folder where the file currently being used by 12d Model resides. This will be unavailable (greyed out) if the user doesn't have access to the folder.

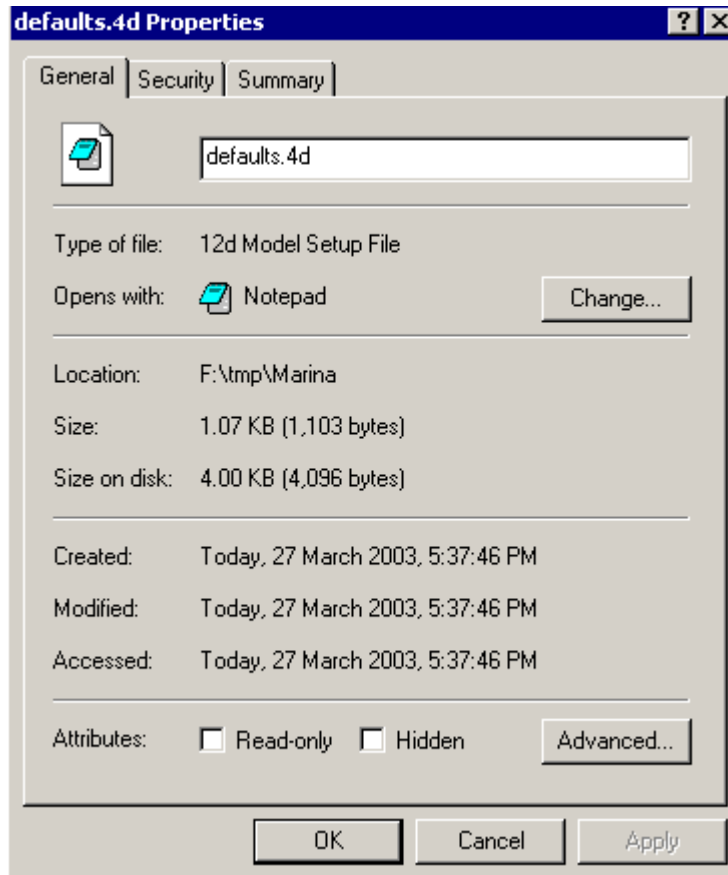

Current folder - the folder where the project currently being used by 12d Model resides. This will be unavailable (greyed out) if the user doesn't have access to the folder.

User folder - the User folder. This will be unavailable (greyed out) if the user doesn't have access to the folder.

Other folder - any folder can be selected.

If you are having problems writing to the file, click on the **Properties** button to bring up the **Properties** panel for the selected file (if it exists) and check the *Security* for the file.

Library, User Library

Apart from set up files which are only accessed when a project is opened or first created, there are two special library areas, one supplied by 12D Solutions Pty Ltd and the other for the user, which are searched for files with the appropriate file ending whenever the folder icon at the end of a panel file field is selected.

For example, clicking on the folder icon for a plot parameter file panel field would display a list of files ending in **.ppf**.

Library

The first library is the folder pointed to by the environment variable

LIB_4D

or if that doesn't exist, in a folder called **library** directly under **7.00**.

The files in **library** are listed under the [Lib] walk right of pop-ups.

Although users can place their files in the **library** folder, it is not recommend since they may be overwritten during future 12d Model installations.

Consequently there is a special user library folder called **user_lib** where user specific files should be placed.

User Library

The second library, the user library, is also a folder and is pointed to by the environment variable

USER_LIB_4D

or if that doesn't exist, in a folder called **user_lib** directly under **7.00**.

The files from the user library are listed under the [User Lib] walk right of the pop-up.

Note

1. The list of special endings for files is given in the Appendix, Special File Formats.
2. A full list of environment variables is given in the later section "Environment Variables".

Environment Variables

When 12d Model is invoked for a new or existing project, it uses environment variables to tailor the system.

In Windows, environment variables can be set for each User from the Control Panel, but a much easier method to set the environment variables used by 12d Model is to include them in a special file which is read in each time a project (new or existing) is opened by 12d Model.

The environment variables that 12d Model recognises can be broken into two types - one type where the environment variable is only a flag setting a mode, and a second type which point to a file, program or folder. For the environment variables of the second type, a default file/program is often searched for if the environment variable is not defined.

The folder search order for the default files for the type group of environment variables is given in the previous sections.

The list of environment variables will just be given in alphabetical order but it will be obvious from the documentation which type the environment variable is.

For environment variables that simply set a flag or value is (the default value is shown in bold) the documentation will be:

Variable Name	Value	Description	Default
---------------	-------	-------------	---------

For environment variables that point to a file, program or folder, and their associated default files/programs, the documentation will be:

Environment Variable Name	Type	Default
---------------------------	------	---------

Alphabetical Environmental Variables List

AUTHORIZATION_4D	full path name	HOME_4D\nodes.4d
------------------	----------------	------------------

The authorization file is normally called **nodes.4d**, and is under the folder **12d model**. However, the file name and path can be set by the user with the environment variable. The full path-name of the file is given.

The default is HOME_4D\nodes.4d.

AUTO_DELETE_WALKRIGHTS_4D	0 <i>pixels</i>	Use old method from V3.1 Distance in pixels to move past the end of the last menu before the cascade collapses	32
---------------------------	---------------------------	---	-----------

If non zero, the environment variable AUTO_DELETE_WALKRIGHTS_4D sets the distance in pixels that is used to collapse the cascade of walk-right menus when the cursor moves that distance past the end of the last walk-right menu.

The default value is 32.

AUTO_RESET_SELECT_4D	0	Don't use auto-reset reselect	
	1	Use auto-reset reselect	<i>default 1</i>

The reset mechanism for picking has ben modified for V5.0 and above. Reset is now done automatically if the cursor is moved a user specified distance (given by AUTO_RESET_TOLERANCE_4D) after a pick (without accepting), and a separate user specified distance (given by AUTO_RESET_DRAG_TOLERANCE_4D) after a directional pick (without accepting).

The default value is 1.

AUTO_RESET_DRAG_TOLERANCE_4D	<i>value</i>	Reset distance for directional picks	<i>default 50</i>
------------------------------	--------------	--------------------------------------	-------------------

If auto-reselect is set on (see AUTO_RESET_SELECT_4D) then this is the distance in pixels to move the cursor to reset the picking rejection list for a directional pick.

The default value is 50.

AUTO_RESET_TOLERANCE_4D	<i>value</i>	Reset distance for non-directional picks	<i>default 5</i>
-------------------------	--------------	--	------------------

If auto-reselect is set on (see AUTO_RESET_SELECT_4D) then this is the distance in pixels to move the cursor to reset the picking rejection list for a non-directional pick.

The default value is 5.

BISECTORS_4D	0	Don't use bisector section use two sections instead.	<i>default 0</i>
	1	Use bisector section	

When applying templates to a horizontal intersection point with a sharp change of direction, (that is, it is not an end point and the HIP has no curve on it and there is a change of direction at the HIP), either two sections can be applied at the HIP point (applied perpendicular to the line on either side of the HIP point) or just a single bisector section applied to the bisector of the change of angle through the HIP.

The default value is 0.

CIVILCAD_PATH_4D	folder	no default
------------------	--------	------------

the full path-name of the folder for CivilCAD files.

There is no default.

COLOURS_4D	filename	default colours.4d
------------	----------	--------------------

file of colour rgb definitions and names. See "Colours" .

The default is colours.4d.

CUBED_CHARACTER_4D	<i>integer (base 10)</i>	<i>default 179</i>
--------------------	--------------------------	--------------------

The integer (base 10) value of the character to use as the cubed symbol.

DATA_COLLECTOR_4D	data collect name
-------------------	-------------------

the data collector that is used if no data collector is set for a project.

There is no default.

DATA_COLLECTORS_4D	filename	default survey.4d
--------------------	----------	-------------------

file of definitions of available data collectors

The default is survey.4d.

DATA_TIPS_4D	0	Don't show data tips	<i>default 0</i>
	1	Show data tips	

When set, data tips are displayed when the cursor moves over point in a plan view.

The default value is 0.

DEFAULTS_4D	filename	default defaults.4d
-------------	----------	---------------------

file of defaults - only used for new project

The default is defaults.4d. See "Defaults" .

DEFAULT_PLAN_SCALE_4D	<i>value</i>	Value is the scale (1:value) for new plan views
-----------------------	--------------	---

If a value is given, then it is used the default scale for any new plan view created in a project. Note that the scale is only used for displaying text defined in paper units in the plan view.

DEFAULT_VIEW_COLOUR_4D	<i>colour_number</i>	<i>default 0</i>
------------------------	----------------------	------------------

The default background colour for views.

DEFAULT_TABLE_WIDTH_4D *number_of_characters* *default 32*

Gives the number of characters displayed in tables such as decisionals and mtf editor.

The default value is 32.

DEGREES_CHARACTER_4D *integer (base 10)* *default 176*

The integer (base 10) value of the character to use as the degrees symbol.

DIAMETER_LARGE_CHARACTER_4D *integer (base 10)* *default 216*

The integer (base 10) value of the character to use as the large diameter symbol.

DIAMETER_SMALL_CHARACTER_4D *integer (base 10)* *default 248*

The integer (base 10) value of the character to use as the small diameter symbol.

DIGITIZERS_4D filename default digitize.4d

file of digitizer definitions

The default is digitize.4d. See "Digitizer Definitions File" .

DISABLE_MTF_WARNINGS_4D **0** Display the mtf warnings in the text editor *default 0*
 1 Write mtf warnings to the background window

Controls whether the mtf warnings go to a file or to the output window.

The default value is 0.

DONGLE_4D parameters

used for network dongles. See the separate notes on installing a network dongle for more details.

DOUBLE_CONFIRM_DELETE_4D **0** Confirm deletes/cleans without undos once
 1 Confirm deletes/cleans without undos twice. *default 1*

Controls whether or not the user is asked once or twice to confirm that deletes and cleans that do not have undos are to be done.

The default value is 1.

DRAINAGE_4D filename default drainage.4d

file of definitions for drainage option

The default is drainage.4d.

DRAINAGE_PPF_4D *full path name of .ppf file* no default

Points to the file used as the default plot parameter file (.ppf) for the panel **New Plot Drainage Network**.

The path name to the .ppf file can contain \$LIB which expands out to the path of the library area. For example, "\$LIB/drainage.ppf" points to the file drainage.ppf in the area defined by \$LIB_4D.

DRAINAGE_FLOW_DIR_4D **0** Flow direction is in descending chainage *default 0*
 1 Flow direction is in ascending chainage

Defines the default flow direction used in the creating a drainage string.

The environment variable **DRAINAGE_FLOW_DIR_4D** specified whether the default flow direction that appears in the **Create Drainage String** panel is that the flow direction in the line is in ascending chainage (that is, the flow is in the same direction as the direction of the drainage string) or that the flow direction in the drainage line is in descending chainage (that is, the flow is in the opposite direction to the direction of the drainage string).

The default value is 0.

EDITOR_4D		script/program	7.00\cpu_area\te
the script or program that is fired up when a report is created. It usually points to an editor.			
If the parameter display reports in the panel sys default settings (given by the menu option Utilities => Default=>Sys defaults) is set to yes , the editor displays each report as it is created.			
The default is '7.00\cpu_area\te'.			
ENVIRONMENT_4D		full path name of file	default env.4d
It is possible to set all the environment variables from a file normally called env.4d . The environment variable file is searched for in the standard set up areas (local, USER_4D, user, set_ups) or is set by the environment variable ENVIRONMENT_4D.			
The default is env.4d.			
The format of the environment variable file is given in the section "Setting Environment Variables".			
EXTRA_OPTIONS_4D		file	default xtramenu.4d
Xtra menu definition			
The default is xtramenu.4d. See "User Defined Menus"			
FAST_ACCEPT_4D	0	don't use fast accept	default 0
	1	use fast accept	
Used for picking items - if fast accept is turned on (1), then when an item is picked and there is only one item in the selection list, that item is automatically selected without a MB being needed.			
The default value is 0.			
FONTS_4D		filename	default fonts.4d
font definitions			
The default is fonts.4d. See "Textstyles and Fonts"			
FUNCTION_KEYS_4D		filename	default userkeys.4d
function key definitions			
The default is userkeys.4d. See "User Defined Function Keys"			
GENIO_WILDCARD_4D	text		default "*.mos"
Sets the ending of the files selected for the pop-up list for the File field in the Read Genio Data panel.			
The default value is "*.mos".			
GUI_4D	Standard		default Standard
	Non Standard		
Defines the mouse button usage within 12d Model.			
The default value is <i>Standard</i> .			
GUI_COLOURS_4D		filename	default gui.4d
file of colour definitions used in the GUI			
The default is gui.4d. See "GUI"			
HARDWARE_ARCS_4D	1	Use hardware arcs	default 1
	0	Hardware arcs are not used	
The default value is 1.			
HEIGHT_MAX_DEFAULT_4D		integer	
set the default value to use in Plan Settings panels that have a Height max (w) field.			

The default value is 0.

HELP_4D		folder	default 7.00\help
---------	--	--------	-------------------

folder containing the 12d Model help files.

The default is '7.00\help'.

HELP_BUTTONS_4D	0	Disable help buttons on panels	<i>default 0</i>
	1	Enable help buttons on panels.	

The default value is 0.

HIMETRIC_4D	0	Printer resolution of 0.04 mm - for Win 95,98,ME	
	1	Printer resolution of 0.01 mm - for Win NT, 2000, XP	

For Windows 95, 98 and ME, the printer resolution can only be 0.04 mm when covering an A0 sheet.

Under Windows NT, 2000 and XP, no such restriction exists and the full resolution of 0.01 mm can be used so the environment variable HIMETRIC_4D allows access to the higher resolution for Windows NT, 2000 and XP.

The default value is 0.

See also WINDOWS_PRINTERS_4D for enabling access to Windows printers.

HOME_4D		folder	three folder levels up from where 12d.exe is
---------	--	--------	--

12d Model home folder

LIB_4D		folder	HOME_4D\7.00\library
--------	--	--------	----------------------

12D Solutions library folder for input files such as mapping, template and macros (4DML's).

The default is 'HOME_4D\7.00\library'.

LINESTYLES_4D		filename	default linestyl.4d
---------------	--	----------	---------------------

file of linestyle definitions

The default is linestyl.4d. See "Line Styles"

LIST_POPUPS_4D	1	Pop-up lists as scrolling lists	<i>default 1</i>
	0	Pop-up lists as menus as in versions up to V3.2	

Defines the look of pop-up lists.

The default value is 1.

LOOK3D_4D	1	3D look and greenish background	<i>default 1</i>
	0	Original 12d gui colours	

The default value is 1.

LOG_DIR_4D		folder-path-name	default is local folder
------------	--	------------------	-------------------------

An error log file is created each time 12d Model is invoked. The error log name automatically created by 12d Model and has the form:

log?????.4de

where ????? is a hashed number using your login name, process id & the current time.

The **folder** that the error log file is created in is given by the environment variable LOG_DIR_4D. The full path-name of the folder is given.

If LOG_DIR_4D is not used, 12d Model tries to create the log file in the current folder, the HOME folder, the TMP folder and the TEMP folder.

If creating an error log file fails in all these ares, 12d Model does not create an error log file.

LONG_SECTION_PPF_4D	<i>path name to .ppf file</i>	no default
<p>This environment points to the file used as the default plot parameter file (.ppf) for the panel section long plot.</p> <p>The path name to the .ppf file can contain \$LIB which expands out to the path of the library area. For example, "\$LIB/long.ppf" points to the file long.ppf in the area defined by \$LIB_4D.</p>		
MACRO_INPUT_MODE_4D	0 1	Don't put current value into the console Put current value into console. <i>default 0</i>
<p>Controls whether or not the value passed down in the variable to receive the answer for any macro prompt, is actually placed into the console panel as the default answer so that it can be accepted by just typing <enter> into the console panel.</p> <p>The default value is 0.</p>		
MIDDLE_DOT_CHARACTER_4D	<i>integer (base 10)</i>	<i>default 183</i>
<p><i>The integer (base 10) value of the character to use as the squared symbol.</i></p>		
MODEL_FOR_TIN_PREFIX_4D	"pre*pos"	<i>default is "tin "</i>
<p>This environment variable is used to customize the default model for the tin in the panels for creating triangulations. Text can be defined for prepending and/or appending to tin name to create a default model name from the tin name.</p> <p>The text for prefixing and postfixing is given in a special form: "pre-text*post-text"</p> <p>If pretext only, just give the text. If post text is required, precede it by a *.</p> <p>If the environment variable is not set, the default "tin " is used.</p>		
MODEL_VIEW_WALKRIGHTS_4D	0 1	Use data source in options Walk-rights for model/view as in up to <i>default 0</i>
<p>V3.2</p> <p>Defines whether the Data source field is used instead of model/view walk-rights used in V3.2.</p> <p>The default value is 0.</p>		
MOVIE_4D	executable	default xanim
<p>X-Windows only - program for running perspective movie</p>		
MS_SEEDFILES_4D	folder	no default
<p>folder of Microstation seed files</p>		
MTF_TMP_4D	anything	not defined
<p>If defined, then the temporary files for mtf calculations go to the Windows temp folder. This is to get over a bug in Novell under Windows 95.</p>		
NAME_MAPPINGS_4D	filename	default names.4d
<p>A mapping file can be specified which is used to fill out information such as colour, model etc. for given string names.</p> <p>The mapping works in two ways. After typing part or all of a string name,</p> <p>(a) if <enter> is entered, the map file is searched for a match in the first column. If a match is found, the name, colour, model, style etc. from the other columns in the mapping file are used to fill out the panel fields.</p> <p>(b) if a <tab> is entered, the second column is searched for a list of completions (if a * is found, the first column is used for that check) which are displayed in a pop-up. When an entry is selected from the completion list, the name, colour, model, style etc. from the columns in the mapping file are used to fill out the panel fields.</p>		

NEVER_SNAP_ITSELF_4D	1	Try to stop a string snapping to itself during editing	
default			
	0	Let a string snap to itself - behaviour in V3.2	

Tries to stop a string snapping to itself during editing.

The default value is 1.

NEW_DRAINAGE_PPF_4D	<i>full path name of binary ppf file</i>		no default
---------------------	--	--	------------

Points to the file used as the default binary plot parameter file (.drainppf) for the long section plot produced by the panel **Drainage Plot PPF Editor**.

The path name to the binary ppf file can contain \$LIB which expands out to the path of the library area. For example, "\$LIB/drainage_long.drainppf" points to the file drainage_long.drainppf in the area defined by \$LIB_4D.

NEW_DRAINAGE_MELB_PPF_4D	<i>full path name of binary ppf file</i>		no default
--------------------------	--	--	------------

Points to the file used as the default binary plot parameter file (.melbppf) for the long section plot produced by the panel **Sewer Plot Melbourne Water PPF Editor**.

The path name to the binary ppf file can contain \$LIB which expands out to the path of the library area. For example, "\$LIB/melb_water.melbppf" points to the file melb_water.melbppf in the area defined by \$LIB_4D.

NEW_DRAINAGE_PLAN_PPF_4D	<i>full path name of binary ppf file</i>		no default
--------------------------	--	--	------------

Points to the file used as the default binary parameter file (.drainplanppf) for the plan annotation produced by the panel **Drainage Plan Plot PPF Editor**.

The path name to the binary ppf file can contain \$LIB which expands out to the path of the library area. For example, "\$LIB/drainage_plan.drainplanppf" points to the file drainage_plan.drainplanppf in the area defined by \$LIB_4D.

NEW_LONG_SECTION_PPF_4D	<i>full path name of binary ppf file</i>		no default
-------------------------	--	--	------------

Points to the file used as the default binary plot parameter file (.lplotppf) for the long section plot produced by the panel **Section Long Plot PPF Editor**.

The path name to the binary ppf file can contain \$LIB which expands out to the path of the library area. For example, "\$LIB/long_section.lplotppf" points to the file long_section.lplotppf in the area defined by \$LIB_4D.

NEW_PLOT_FRAME_PPF_4D	<i>full path name of binary ppf file</i>		no default
-----------------------	--	--	------------

Points to the file used as the default binary parameter file (.plotframeppf) for the plan plot produced by the panel **Plot Frame PPF Editor**.

The path name to the binary ppf file can contain \$LIB which expands out to the path of the library area. For example, "\$LIB/plot_frame.plotframeppf" points to the file plot_frame.plotframeppf in the area defined by \$LIB_4D.

NEW_X_SECTION_PPF_4D	<i>full path name of binary ppf file</i>		no default
----------------------	--	--	------------

Points to the file used as the default binary plot parameter file (.xplotppf) for the cross section plots produced by the panel **Section X Plot PPF Editor**.

The path name to the binary ppf file can contain \$LIB which expands out to the path of the library area. For example, "\$LIB/cross_section.xplotppf" points to the file cross_section.xplotppf in the area defined by \$LIB_4D.

PAN_MODE_4D	0	Use pan for pan, pans on views	<i>default 0</i>
	1	Use pan deltas for pan, pans on views	

Sets whether pan or pan delta is used for the pan and pans buttons on views.

The default value is 0.

PLAN_TABLE_SETTINGS_4D	0	Don't allow setting by model	<i>default 0</i>
	1	Allow setting by model	

Trial only - allow the drawing of z-values, vertices etc. on the plan view to be set by individual models rather than for all models on the view.

The default value is 0.

PLOTTER_4D	script/program	no default
------------	----------------	------------

This environment variable points to a script/program which can be fired up whenever a plot is generated. The name of the plot is given as the first script parameter of the script.

If the parameter **Send plots** on the 'System Settings' tab of the menu option **Utilities => Defaults** is set to **yes**, the plotter script is run as each plot is created.

If more than one plot is created by an option (e.g. x plot) then the script is called separately for each of the plots.

An example of a script to send the plot to port lpt1 for Windows NT would be

```
@echo off
copy %1 lpt1
```

An example for Windows NT which looks for hp files is

```
@echo off
echo.
echo -----
:next_file
if "%1" == "" goto done
echo %1 | find /I ".hp" > nul
if ERRORLEVEL 0 if not ERRORLEVEL 1 goto hp_plotter
echo Plotting file %1
shift
goto next_file
:hp_plotter
echo Plotting %1 to HP plotter
shift
goto next_file
:done
echo -----
```

PLOTTER_MAPPING_4D	filename	default pmf.4d
--------------------	----------	----------------

This points to the file which is used as the default plotter mapping file. The format for the plotter mapping file is described in the section "Mapping Colours to Plotter Pens" in the Appendix "Set Ups".

The default is pmf.4d.

PLOTTERS_4D	filename	default plotters.4d
-------------	----------	---------------------

This points to the file which contains user defined plotters. The format for the file of user defined plotters is described in the section "User Defined Plotters" in the Appendix "Set Ups".

The default is plotters.4d.

PLOT_SYMBOLS_4D	filename	default plotsymb.4d
-----------------	----------	---------------------

Points to the file used to define the symbols used in long and cross section plots.

The default is plotsymb.4d.

POLYPOLYLINES_4D	0	Don't use speed ups	<i>default 0</i>
------------------	----------	---------------------	------------------

1	Intermediate speed ups
2	Faster speed ups.

A few experimental techniques are available for speeding up the drawing on the screen.

For some specific things such as fast contours, fast mesh and point crosses, the techniques can result in some redraws being up to three times faster.

The default value is 2.

PRINTER_4D script/program no default

Points to a script or program which can be fired up whenever a report is generated. The name of the report is given as the first parameter of the script.

If the parameter **Print reports** on the 'System Settings' tab on the menu option **Utilities => Defaults** is set to **yes**, the printer script is run as each report is created.

PROJECT_NAMES_4D 0 Use long filenames for internal files as used by all versions up to and including V3.0 *default 0*
1 Use short names

The use of long or short extension names for internal 12d Model files for items such as models, tins, templates etc. is controlled by the environment variable **PROJECT_NAMES_4D**.

Opening a new project with the short name format, project-name.4dp, will automatically create a short name project (i.e. a project using the short extension names).

The default value is 0.

RECENT_PROJECTS_4D positive integer default 20

The maximum number of accessed projects displayed when 12d Model starts up.

REPORT_HEADER_4D 0 Report files have no header page
1 Some header information is used
2 A full header page is produced. *default 2*

Controls the amount of header information in reports.

For the cases 1 and 2, the header information includes

- the 12d Model Project
- the name of the user
- the organization
- the current date
- the current report file name

The default value is 2.

RUN_MACROS_FILE_4D filename default macros.4d
file of macros (one per line) that are run when a new project is created - only for new projects
The default is macros.4d

SETUPS_FILE_4D filename default setups.4d
file setting up the initial screen layout for new projects
The default is setups.4d. See "Set Ups".

SET_UPS_4D folder HOME_4D\7.00\set_ups
folder for storing the standard set up files installed by 12D Solutions.
The default is 'HOME_4D\7.00\set_ups'.

SEWER_PPF_4D		<i>path name to .ppf file</i>	no default
	points to the file used as the default plot parameter file (.ppf) for the panel new plot sewer network .		
SHEET_SIZES_4D		filename	default sheets.4d
	For plot frames, long and x plots, the overall size of the plot sheet can be given by a pop-up containing defined sheet size.		
	The sheet size name and width and heights can be specified by the user in a file named sheets.4d which is in the normal set up areas, or is pointed to by the environment variable SHEET_SIZES_4D.		
	The default is sheets.4d. See "Sheet Sizes" .		
SHOW_PATHS_4D		anything	
	If defined, then when 12d Model fires up the actual file names defined by any environment variables are written to the output window. This is useful for debugging.		
SHOW_TITLE_VARIABLES_4D		0	Any \$variable not used is left as blank
		1	Any " not used is shown as \$variable
		2	All " are plotted with no substitution
	For debugging the title block file.		
	The default value is 0.		
SPIRALS_4D		filename	default spirals.4d
	file of spiral definitions		
	The default is spirals.4d. See "Spirals" .		
SQUARED_CHARACTER_4D		<i>integer (base 10)</i>	<i>default 178</i>
	<i>The integer (base 10) value of the character to use as the squared symbol.</i>		
STATION_PREFIX_4D			
	There is no default.		
	The default prefix to use in the Survey Data Setup panel or to use if prefix has been set for the project.		
	There is no default value.		
SUPER_STRING_4D		1	Use the super string
		0	Don't use the super string.
			<i>default 1</i>
	Controls whether the super string is accessible or not.		
	The default value is 1.		
SYMBOLS_4D		filename	default symbols.4d
	Points to the file used to define the symbols used for super strings.		
	The default is symbols.4d.		
SYSTEM_NAMES_4D		1	Only use the old longer names
		2	Only use the 8.3 file names
		3	Use short names first,
			then look for a long name.
			<i>default 3</i>
	From 12d Model V3.1 onwards, the default names for all set up files fit in with the DOS 8.3 format. For compatibility, it is possible to use both the old longer names and the new short file names.		
	The default value is 3.		
TEXTSTYLE_MAPPINGS_4D		filename	default textstyle_names.4d
	file of textstyles favourites definitions		
	The default is textstyle_names.4d		

TEXTSTYLES_4D		filename	default textstyl.4d
		file of textstyles definitions	
		The default is textstyl.4d. See “Textstyles and Fonts” .	
TICK_DRAW_CROSS_4D	0	Nothing for off	default 0
	1	Cross for off	
		The default value is 0.	
TIN_VIEWPORT_CLIP_4D	0	Drawing tins, fast contours as per V3.1	default 0
	1	A speed up for drawing tins, fast contours	
		Use some experimental techniques for speeding up the drawing of tins, fast contours.	
		The default value is 0.	
TOOLBARS_4D		filename	default toolbars.4d
		file of toolbar definitions and names	
		The default is toolbars.4d. See “User Defined Toolbars”	
TYPED_UNITS_MODE_4D	0	International units only e.g. f and F are both International feet	default 0
	1	USA units only e.g. f and F are both US feet	
	2	Mixed e.g. f is International feet and F is US feet.	
		Controls the typed input units for feet - international and/or US. The default value is 0.	
UNDO_4D	0	Don't allow undo's	
	1	Allow undo/redos.	default 1
		Undo and Redo is available for most operations from 12d Model V3.1 onwards. The availability of Undo/Redo facility is controlled by the environment variable:	
		The default value is 1.	
USAGE_LOG_4D		folder	no default
		when set, log files of the form	
		<log file folder>\(<dongle> <user> <computer> <time stamp> <process ID>.log)	
		will be created in the given folder.	
USAGE_LOGS_4D		folder	no default
		when set, log files of the form	
		<log file folder>\<dongle>\<user>\<computer>\(<time stamp> <process ID>.log)	
		will be created in the given folder.	
USER_4D		folder	HOME_4D\7.00\user
		user folder containing set up files	
		The default is 'HOME_4D\7.00\user'.	
USER_LIB_4D		folder	HOME_4D\7.00\user_lib
		user library folder for input files such as mapping, template and macros (4DML's).	
		The default is 'HOME_4D\7.00\user_lib'.	
USER_OPTIONS_4D		file	default usermenu.4d
		To help customise 12d Model, the walk-right menu User on the main 12d Model menu, can be user defined. The text for each button of User , plus the action taken when the button is selected is user specified. Any of the buttons can include further walk-right menus.	

The definition for User is given in a file with the default name usermenu.4d which is searched for in the standard set up areas (local, USER_4D, user, set_ups) or set by the environment variable USER_OPTIONS_4D.

The default is usermenu.4d. See "User Defined Menus"

VEHICLE_PATH_4D		folder	no default
Vpath is the Vehicle Turning Path program written by Main Roads Queensland and is a separate chargeable program.			
The environment variable VEHICLE_PATH_4D points to the folder where the Dos version of the Vpath executable is located. Note that WINDOWS_VEHICLE_PATH_4D points to the Windows version.			
VIEW_BITMAP_BUTTONS_4D	0	User text for view buttons	
	1	Use icons for view buttons	default 1
The default value is 1			
VIEW_BUTTONS_4D	0	No view buttons are displayed	
	1	The view buttons are displayed	default 1
The default value is 1			
WARP_CURSOR_HIDE_4D	0	Don't hide the cursor before moving it	default 0
	1	Hides the cursor before moving it	
Controls whether the cursor is hidden before moving - only needed on some computers.			
The default value is 0.			
WEB_4D		search engine web address	www.google.com
web address of the search engine that is fired up from the 12d option			
<i>Help =>12d on the Web =>Search the web.</i>			
WEED_TOLERANCE_4D	0	Don't weed	
	real	Weed tolerance	
used in Alignment and Super strings so that when arcs have been chord-to-arc'd, the resulting points are weeded so that no point is closer than the weed tolerance. Is also used in Apply and Apply Many so that no cross sections are closer than the weed tolerance.			
WINDOWS_PRINTERS_4D	0	Don't allow Windows printers	
	1	Enable Windows printers	default 1
The default value is 1.			
WINDOWS_VEHICLE_PATH_4D		folder	no default
Vpath is the Vehicle Turning Path program written by Main Roads Queensland and is a separate chargeable program.			
The environment variable WINDOWS_VEHICLE_PATH_4D points to the folder where the Windows version of the Vpath executable is located.			
WINTER_4D		path name to WINTER program	
points to the WINTER program for calculation N-values for Australia.			
WINTER_DATA_4D		folder	no default
Folder containing the Winter data of N-values for Australia.			
WRITE_ALL_PLOT_PARAMETERS_4D	0	Only write out the plot parameters that are used in the ppf.	
	1	Write out all plot parameters	
default 1			

Controls whether all plot parameters are written out or just those that have been used in the ppf file.

The default value is 1.

X_SECTION_PPF_4D *path name to .ppf file* no default

points to the file used as the default plot parameter file (.ppf) for the panel **section X plot**.

The path name to the .ppf file can contain \$LIB which expands out to the path of the library area. For example, "\$LIB/cross.ppf" points to the file cross.ppf in the area defined by \$LIB_4D.

ZOOM_ORIGIN_DYNAMIC_4D **0** The centre of the view is the zoom centre point *default 0*
1 The point you pick is the zoom centre point

Controls the origin of the dynamic zoom. If set then the point selected in the view to indicate which view to dynamically zoom (and to be the zoom in-zoom out definition point) becomes the point to dynamically zoom about. Whilst the dynamic zoom is running, another point can be selected to become the new zoom origin.

The default value is 0.

ZOOM_PAN_DYNAMIC_4D **0** *Dynamic pan is not the default* default 0
1 Dynamic pan is the default for pan

If set then dynamic pan is the default for the pan options. The middle mouse button (or 'd') is not required to place the pan option in dynamic mode. In fact, it would then toggle it off.

The default value is 0.

Notes

- (a) If any of the environment variables (pointing to files) are not set, or the file pointed to does not exist, then 12d Model searches for the default files in a number of locations. The search order is given at the beginning of this Appendix.
- (b) The eagle pen mapping file, **eagleplt.emf** is also searched for in the same order as the default files.
- (c) When an **existing** project is opened by 12d Model, the setups.4d and defaults.4d are not used.

Setting Environment Variables

The simplest method for setting the required environment used in 12d Model is to place them into a file, called the environmental file (default name env.4d).

Environment Variables File

It is possible to define a file which sets the value for one or more environment variables.

The file format consists of one line for each environment variable being set and each line contains the environment variable name, followed by one or more spaces and then the value for the environment variable:

```
environment_variable_name      value
```

The value of any environment variable given in the environment variable file **overrides** any other definition for that environment variable.

The file used as the environmental variable file is checked for in the following order - as soon as a file is found, the search terminates and that file is used:

1. as a command line argument when 12d Model is fired up. The syntax is

```
12d -env path_name
```

where path_name is the full path name of the file

2. pointed to by the environment variable ENVIRONMENT_4D

```
ENVIRONMENT_4D    file           // file of environment variables
                  // default env.4d
```

3. a file called **env.4d** which is searched for in the standard set up areas (local, USER_4D, user, set_ups).

An example of an environment variable file is

```
EDITOR_4D         te           // set the text editor used
SHOW_PATHS_4D    1           // show file names set by environment variables
SHEET_SIZES_4D   c:\standards\shfile
```

Setting Environment Variables not in a File

Environment variables can be set in **Windows NT** for a user from the *Environment* tab on the *System Properties* panel brought up by clicking on the *System* icon in the *Control Panel* of Windows.

To bring up the *Control Panel*, click on *Start* in the Windows Task bar, walk right on *Settings* and then click on *Control Panel*.

Set Ups

The set up file, **setups.4d**, is used to define the initial screen set-ups. It can be used for

- s the system font used for text
- s the size of the initial window
- s the position of the main menu, header menu, function menu, function recalc menu, snaps menu, volumes menu, geometry menu, sewer menu, pipeline menu
- s the position of the screen message box, xyz message box
- s the position of the **save project** panel (now redundant)
- s the position, size, name and viewing parameters for the initial views

The co-ordinate system used for specifying the position of the left hand top corner of items on the screen is by column and row. For items which include an area of the screen (such as the window and views), a width and depth are also specified.

The column value is measured from the left hand size of the screen and the row value is measured from the top of the screen.

The units for row, column, width and depth are screen pixels.

Note - If any views are defined in the set_up_file, then the position of the **screen message box** must be also be defined and it must be **before** the definition of any view.

The format of the commands in the file setups.4d is

```

WINDOW          column_value  row_value  width      depth // main window

MAIN MENU
                column_value  row_value

FUNCTION MENU
                column_value  row_value
FUNCTION RECALC MENU
                column_value  row_value
GEOMETRY MENU
                column_value  row_value
PIPELINE MENU
                column_value  row_value
SEWER MENU
                column_value  row_value
SURVEY MENU
                column_value  row_value
VOLUMES MENU
                column_value  row_value

SNAPS MENU
                column_value  row_value
SNAPS BUTTONS HORIZONTAL
                column_value  row_value
SNAPS BUTTONS VERTICAL
                column_value  row_value

PROJECT SAVE PANEL
                column_value  row_value

// Views

PLAN VIEW      column_value  row_value  width      depth      name

```

SECTION VIEW	<i>column_value</i>	<i>row_value</i>	<i>width</i>	<i>depth</i>	<i>name</i>
PERSPECTIVE VIEW	<i>column_value</i>	<i>row_value</i>	<i>width</i>	<i>depth</i>	<i>name</i>
reference point	0.0	750.0	120.0	// x y z	
view plane normal	1.0	0.0	0.0	// dx dy dz	
view up vector	0.0	0.0	1.0	// dx dy dz	
view distance	10.0			// distance	

The following parameters were used for V5.00 but are ignored for V5.0 onward:

SCREEN MESSAGE BOX	<i>column_value</i>	<i>row_value</i>
XYZ MESSAGE BOX	<i>column_value</i>	<i>row_value</i>

Colours

12d Model allows the use of up to **10,240** distinct colours for drawing in any view.

The colours are numbered from 0 to **10,239** and the user defines the red, green and blue mix (RGB) for each colour and what name is used throughout the program when referring to the colour.

The colour names and RGB mix associated with each colour number is defined in the file **colours.4d**.

The format for each line of the *colours.4d* file is:

```
red_value green_value blue_value pen_num col_name col_num pop-up_num col_group
```

Each colour is defined in terms of its red, green and blue intensity (RGB). The intensity value is between 0 and 255, where 0 represents no colour and 255 full colour. The RGB values for the colour are *red_value*, *green_value* and *blue_value*.

When plotting, the **default plotter pen number** used to plot a colour is given in the file as *pen_num*. The pen number is an integer that is positive or zero.

The actual **colour name** used to describe the colour is given in quotes after the default plotter pen number - *col_name*. Colour names can be alphanumeric although upper and lower case are considered the same. Each colour must have a unique colour name. If an underscore "_" is used in a colour name in the *colours.4d* file then a space is inserted in 12d Model. The colour name must be enclosed within quotes. For example, "dark red".

The **colour number** is what is actually stored in 12d Model and it is given after the colour name - *col_num*. A colour number is an integer that is positive or zero. Colour numbers can only occur once in the *colours.4d* file but there can be gaps in the colour numbers.

The **colour pop-up number**, *pop-up_num* is the next item in the *colours.4d* file.

The colour pop-up number is an integer that can be negative, zero or positive. Colour pop-up numbers can only occur once in the *colours.4d* file but there can be gaps in the colour pop-up numbers.

The *colour pop-up number* is used to decide which colours are should in the Colour box. If *Display colours* is set to *n* in *Utilities => Defaults*, then the colours with the *n* smallest pop-up numbers are displayed in the Colour box pop-up. So the order that the colours are chosen to appear in the colour pop-up is independent of the colour number.

The **colour group**, *col_group*, is the last item in the *colours.4d* file. The colour group is simply text and does not have to be unique. The colour group is enclosed in quotes. For example, "vis".

The colour group is not currently used in 12d Model but is expected to be used to group colours together in a colours pop-up.

The *colours.4d* file is displayed and modified by using the **Edit Colours** panel brought up from the [Edit] item on the colours pop-up, *Select Colour*. For more information, go to the section "Colours" of the Chapter "Tools and Concepts".

Defaults

The **defaults** file, **defaults.4d**, defines the initial default settings used in the 12d Model **default** and the **systems defaults** panels.

The **defaults** file can contain:

```
// general defaults

DEFAULT COLOUR                red
DEFAULT POINT COLOUR          yellow
DEFAULT TIN COLOUR            brown
DEFAULT CONTOUR COLOUR        cyan
DEFAULT CONTOUR INDEX COLOUR  magenta
DEFAULT TEXT SIZE              8

// view settings

DEFAULT CULLING OFF/ON
DEFAULT CULLING SIZE           1.0
DEFAULT SECTION VIEW EXAGGERATION 10.0
DEFAULT PERSPECTIVE VIEW EXAGGERATION 1.0

DEFAULT FAST TEXT CULL SIZE    4.5 // if not specified assumes 4.5
DEFAULT NONE TEXT CULL SIZE    2.0 // if not specified assumes 2.0

// highlighting

DEFAULT ANGLE MODE             BEARINGS/DEGREES
DEFAULT HIGHLIGHT COLOUR       white
DEFAULT HIGHLIGHT CROSS COLOUR yellow
DEFAULT HIGHLIGHT CROSS SIZE   2.0

// drawing points

DEFAULT CHORD ARC TOLERANCE    0.1
DEFAULT POINT CROSS SIZE MMS   2.0
DEFAULT POINT CROSS SIZE PIXELS 3

// trash model and mode

DEFAULT TRASH MODEL            model_name // model for trash
DEFAULT TRASH MODE              trash string // send used strings to trash
                                delete string // delete used strings
                                keep string // keep used strings

// miscellaneous

DEFAULT NAME SETTINGS          file_name // names.4d file
```

The information panel for each editor can be toggled on/off and the initial state when a new edit operation is begun is given by

```
DEFAULT EDIT INFORMATION      1 // show info panel on editor start-up
                              0 // don't show info panel
```

When output report are created, the scripts/programs pointed to by **EDITOR_4D** and **PRINTER_4D** will be run depending on the values of the defaults **display reports** and **print reports**.

```
DEFAULT DISPLAY REPORT FILES  1 // run EDITOR_4D
```

	0	// don't run "
DEFAULT PRINT REPORT FILES	1	// run PRINTER_4D
	0	// don't run "

Similarly when plots are created, the script/program pointed to by PLOTTER_4D and will be run depending on the value of the default **send plots**.

DEFAULT SEND PLOT FILES	1	// run PLOTTER_4D
	0	// don't run "

The number of minutes between displays of the **save project** yes-no box is given by

DEFAULT SAVE INTERVAL	minutes	// 0 for never
-----------------------	---------	----------------

The file defining string colours can have up to 10,240 colours in it however this number is usually inconvenient to display in the standard colour pop-up so there is a setting to set how many colours are displayed from the list.

DEFAULT POPUP COLOURS	number_of_colours	// default 16
-----------------------	-------------------	---------------

The precision for displaying real numbers in the information panel and in boxes and panel fields can be set.

DEFAULT PRECISION	integer	// info panel - default 3
DEFAULT BOX PRECISION	integer	// boxes & panels -default 4

The sign for cut areas and volumes can be positive or negative (fill is the opposite) and is given by

DEFAULT CUT VOLUME SIGN	-1	// negative for cut (default)
	1	// positive for cut

Text in text string, 4d strings and linestyles may be in pixels and must be given a millimetre size for plotting. Pixel text is multiplied by a factor to convert it to a millimetre size. The pixels to mm plot

DEFAULT PIXELS TO MM PLOT FACTOR	real	// default 1.0
----------------------------------	------	----------------

GUI

Note - this section is only for versions earlier than V4.0

The file **gui.4d** defined the colours used for screen objects (the graphical user interface objects), screen fonts, maximum pop-up length, and spacing in the menus and panels.

The gui.4d file is read every time a project (new or old) is opened.

GUI Colours

The colours associated with each screen object are given in terms of intensity values of red, green and blue. The intensity values are between 0 and 255, where 0 represents no colour and 255 full colour.

The layout for screen colours in the gui.4d file is:

```
// object                RGB values- red green blue

VIEW BACKGROUND COLOUR  0  0  0          // black
VIEW BORDER COLOUR     255 255 0        // yellow

BUTTON HIGHLIGHT COLOUR 255 255 0      // yellow
BUTTON TEXT COLOUR     127 127 127     // grey
BUTTON BACKGROUND COLOUR 60  60 200    // dark blue

MENU BACKGROUND COLOUR  150 90  0      // brown
MENU BORDER COLOUR     255 255 0      // yellow

PANEL BACKGROUND COLOUR 150 90  0      // brown
PANEL BORDER COLOUR     255 255 0      // yellow

FRONT SCREEN LOGO COLOUR 255 255 0    // yellow
FRONT SCREEN TEXT COLOUR 0  255 0     // green
FRONT SCREEN BACKGROUND COLOUR 60 60 200 // dark blue

WINDOW BACKGROUND COLOUR 1  64 128  0  // half green
WINDOW BACKGROUND COLOUR 2  0 128 196 // cyan
```

Maximum Pop-Up Length

The maximum number of items in a pop-up list before splitting into walk-right pop-ups is given by (necessary when using VGA screens on PC's)

```
POPUP LENGTH          integer      //maximum number of items in a pop-up
```

Fonts for Menus and Panels

A font can be defined for use in the menu and panel titles areas and a separate font for the rest of the text in the menus and panels.

The fonts are defined in the gui.4d file as:

```
SYSTEM TITLE FONT      font_name      // font for titles
SYSTEM FONT            font_name      // font used elsewhere
```

For X-Windows, the font_name is the name of the required font from the font list given by the command xlsfonts.

For Windows NT, the font_name is made up of the Windows font name plus zero or more parameter values for the font.

The font name and parameter values are given as one text name, font_name, by concatenating the font name and values with only a minus separating them.

If the font name consists of more than one word, the font name is enclosed in double quotes("").

Hence for NT, an example of defining fonts is:

Parameter	Possible Values
Font	font name (less than 32 characters)
Height	number
italic	
underline	
strikeout	
Weight	thin extralight light normal medium semibold bold extrabold heavy
Quality	draft proof
Pitch	default_pitch fixed_pitch variable_pitch
Family	decorative modern roman script swiss

Defaults

Height	14
Weights	fw_dontcare (family weight don't care)
Pitch	font default pitch
Family	ff_dontcare (font family don't care)
Quality	default_quality
italic	false
underline	false
strikeout	false

For example

Arial-14-bold-italic is the font Arial, of height 14 and bold and italic

"Courier New"-16-italic is the font Courier New, of height 16 and bold.

Under NT, if the font is not properly defined or doesn't exist, then the system font is used.

Under X-Windows, if the font does not exist, the font fixed is tried. If fixed does not exist, 12d Model will not start up.

Spacing for Borders and Panels

There are parameter to control the amount of space in border, between items etc. for menus and borders. These are normally set by 12D Solutions and should not need to be modified.

SCREEN TEXT BORDER X	pixels
SCREEN TEXT BORDER Y	pixels
SCREEN TEXT EXTRA X	pixels
SCREEN TEXT EXTRA Y	pixels
EDIT BOX BORDER X	pixels
EDIT BOX BORDER Y	pixels
PANEL BORDER X	pixels

PANEL BORDER Y	pixels
PANEL GAP Y	pixels
VERTICAL BORDER X	pixels
VERTICAL BORDER Y	pixels
VERTICAL GAP Y	pixels
HORIZONTAL BORDER X	pixels
HORIZONTAL BORDER Y	pixels
HORIZONTAL GAP Y	pixels
INPUT BOX BORDER X	pixels
INPUT BOX BORDER Y	pixels

Sheet Sizes

For plot frames, long and x plots, the overall size of the plot sheet can be given by a pop-up containing defined sheet size.

The sheet size names, width and heights can be specified by the user in a file named **sheets.4d** which is in the normal set up areas, or is pointed to by the environment variable

```
SHEET_SIZES_4D    file           // file of plotter sheets sizes
```

The layout of the sheet sizes file is

```
// User definition file for sheets sizes in 12d Model  
// Heights and widths are in mm.
```

```
//      sheet name           width      height  
  
      A0                    1189      841  
      A1                     841      594  
      A2                     594      420  
      A3                     420      297  
      A4                     297      210  
  
      B1                    1000      707
```

Spirals

A spiral curve can be uniquely defined in terms of a start tangent vector, a final radius of curvature (R) and a total spiral length (L).

Traditionally, the equation for this spiral is given in terms of a local co-ordinate system where the origin is at the start of the spiral and the x-direction (abscissa) is along the tangent vector at the start of the spiral. The y-direction (ordinate) is given as the offset from the x-axis of the point on the spiral.

Formulae for the local co-ordinates of a point on the spiral can then be derived in terms of the distance of the point along the spiral (the spiral length to the point) and the given constants L (the total spiral length) and R (the final radius of curvature of the spiral).

These formulae for the local co-ordinates of a point on the spiral are **polynomial series** in terms of the spiral length to that point.

For use in calculations, the local co-ordinates can be **approximated** by restricting the polynomial series to a fixed number of terms.

For example, the **cubic** spiral only uses the first term for the polynomials for x and y.

		number of terms for the		
		cubic	Westrail cubic	clothoid
abscissa	x	1	2	5
offset	y	1	1	4

In 12d Model, the names and the x and y coefficients used for spiral definitions are given in the file **spirals.4d** or in the file pointed to by the SPIRALS_4D environment variable.

The format for each spiral definition in the file is

```

spiral "spiral-name" {
  data {
    x coefficient  y coefficient for the first term
    x coefficient  y coefficient for second term
    x coefficient  y coefficient for third term
    ... for a total of up to ten terms
  }
}

```

For example,

```

spiral "westrail-cubic" {
  data {
    1.0  0.16666666666666666
    0.025  0.0
  }
}
spiral "cubic" {
  data {
    1.0  0.16666666666666666
  }
}

```

Note - the clothoid spiral is the default spiral used in 12d Model and does not have to be defined in the file.

12d Model Options Map

The **12d Model** menu map shows the menu structure for all the sub-menus on the main 12d Model menu and the menus on the views.

The map is designed to be printed out for users who wish to affix it to a wall.

The PDF file of the menu map on the 12d Model Installation CD in the folder

Documentation\12d Model menu map

Or in the *Updates* section of the web site www.12d.com

Monitoring 12d Model Usage

Overview

12d Model usage can be monitored for single-user and network licenses (or a mix of both), whether installed on a single computer, a local-area network, or a wide-area network across different time zones.

Monitoring the usage is a 3 stage procedure:

1. Generating individual .log files for each 12d Model session run.
2. Consolidating all the completed .log files into a CSV file.
3. Reporting the usage details, using the CSV file as input.

The 1st stage is achieved by setting an environment variable in your env.4d file(s).

The last 2 stages are achieved by running the supplied program: 12d_usage.exe.

Generating the .log files

By setting one of two possible environment variables in the env.4d file(s) used for your 12d Model sessions, uniquely named .log files can be generated in a specified folder on your network.

For example, by adding the lines:

```
usage_log_4d F:\12d model usage
```

or

```
usage_logs_4d F:\12d model usage
```

to your env.4d file(s), then each time a 12d Model session is run, a .log file will be created in the “F:\12d model usage” folder. This folder, referred to as the <log file folder>, can be anywhere on your network and can have any name, **but it must be created beforehand**, and all 12d Model users must have write-access to it.

In the first case, using variable “usage_log_4d”, log files will be generated in the form:

```
<log file folder>\(<dongle> <user> <computer> <time stamp> <process ID>).log
```

In the second case, using variable “usage_logs_4d”, log files will be generated within sub-folders of the form:

```
<log file folder>\<dongle>\<user>\<computer>\(<time stamp> <process ID>).log
```

Note that the <time stamp> represents the start time of the 12d Model session in GMT (also known as UTC or Zulu Time).

It does not matter which variable you decide to use, and you can even use a mix of the variables, if you have more than one env.4d file. However, regardless of which variable you use, it is recommended that the <log file folder> is the same for all 12d Model users on your network so that all 12d Model sessions can be easily included in the reports.

The .log file generated in the <log file folder> for each individual 12d Model session run on your network, contains all the information required about that session. While the session is still running, the log file will be updated at a minimum of every 75 seconds, with the time that the session has been active. At the close of the 12d Model session, the log file is again updated and is set as “completed”.

Installing 12d_usage.exe

You can put the 12d_usage.exe program wherever you like on your network. Then, simply create a shortcut to the program on your desktop, making sure the shortcut properties are set as follows:

Target: <path to program location>\12d_usage.exe
Start in: <path to Working Folder>

The Working Folder is the folder that you run the 12d_usage.exe program from (it does not have to be the same as the location of the 12d_usage.exe file). After running the program for the first time, a file named 12d_usage.defaults will be created in the Working Folder. This file is used to save your settings from the last run of the program and to load your settings for the next run of the program. In addition, you might also wish to use the Working Folder to store your 12d Model Usage report files (although you are free to store them elsewhere).

Running 12d_usage.exe

To run the 12d_usage program, simply double-click on the shortcut icon you created at install time. This will open up a DOS window from where the program's keyboard-driven menu system can be run.

From the Main menu within the 12d_usage program, your keyboard-driven menu options are:

C Bring up the Consolidate menu
R Bring up the Report menu
Q Exit (quit) the 12d_usage program

Consolidating the .log files

After a while, you should notice that a lot of .log files are being generated in your specified <log file folder>. To consolidate all these .log files into a single Comma-Separated-Variable (CSV) file, you will need to run the 12d_usage.exe program, and press the "C" key to bring up the Consolidate menu.

From the Consolidate menu, your keyboard-driven menu options are:

F Specify the <log file folder>
O Specify the output CSV file name
T Toggle whether to delete or rename consolidated log files
C **Consolidate 12d Model session log files**
Q Exit the Consolidate menu and return to the Main menu

When specifying the name of the CSV file you wish to consolidate your log files to (using the "O" key), if you want a .csv file extension (to allow the file to be easily loaded into MS[®]Excel for your own custom reports, for example), you must include the .csv in the file name. It is recommended that all users of the 12d_usage program consolidate log files to the same CSV file every time. Newly consolidated logs are always appended to an existing CSV file. If there is to be more than one user of the 12d_usage program, it might be a good idea to specify the CSV file to be in the <log file folder> or the Working Folder (or at least, some folder that all 12d_usage users can access).

You also need to specify how to tidy up the log files, after they have been consolidated, so that they are not consolidated more than once. Your options here are to rename or to delete the log files (the "T" key toggles between rename and delete). If you choose to rename them, they will be renamed with a .logc extension. If you choose to delete them, they will be lost forever, and the only record you will have of your consolidated sessions will be contained in the CSV file. As such, you should be very careful not to delete your CSV file.

Pressing the "C" key will then go ahead and consolidate the log files. Note that consolidation will only take place on "completed" log files (or on log files that have not been updated for more than 24 hours - to handle the case of a power failure, for instance).

Reporting on 12d Model Usage

After creating or adding to your consolidated CSV file, you can press the “R” key from the Main menu, in order to bring up the Report menu.

From the Report menu, your keyboard-driven menu options are:

- I Specify the input CSV file name (generated from the Consolidate menu)
- O Specify the output report file name
- M Toggle whether to overwrite or append to existing report file
- D Add/Remove Dongle constraints
- C Add/Remove Computer constraints
- U Add/Remove User constraints
- F Add/Remove Folder constraints
- P Add/Remove Project constraints
- E Add/Remove Program constraints
- V Add/Remove Version constraints
- T Specify Start and End times for report (in Local Time of 12d_usage User*)
- S Specify which summary tables you want in the report
- R Generate the 12d Model Usage report**
- Q Exit the Report menu and return to the Main menu

After generating the report (using the “R” key), you will be asked if you want to view the report file. If you answer yes (using the “Y” key), the report file will be opened using Notepad.exe as the default file editor. If you would prefer to use a different file editor, you can specify it by manually editing the 12d_usage.defaults file (see Installing 12d_usage.exe), and replacing the word “notepad” (last line of the file), with the command to start your preferred editor.

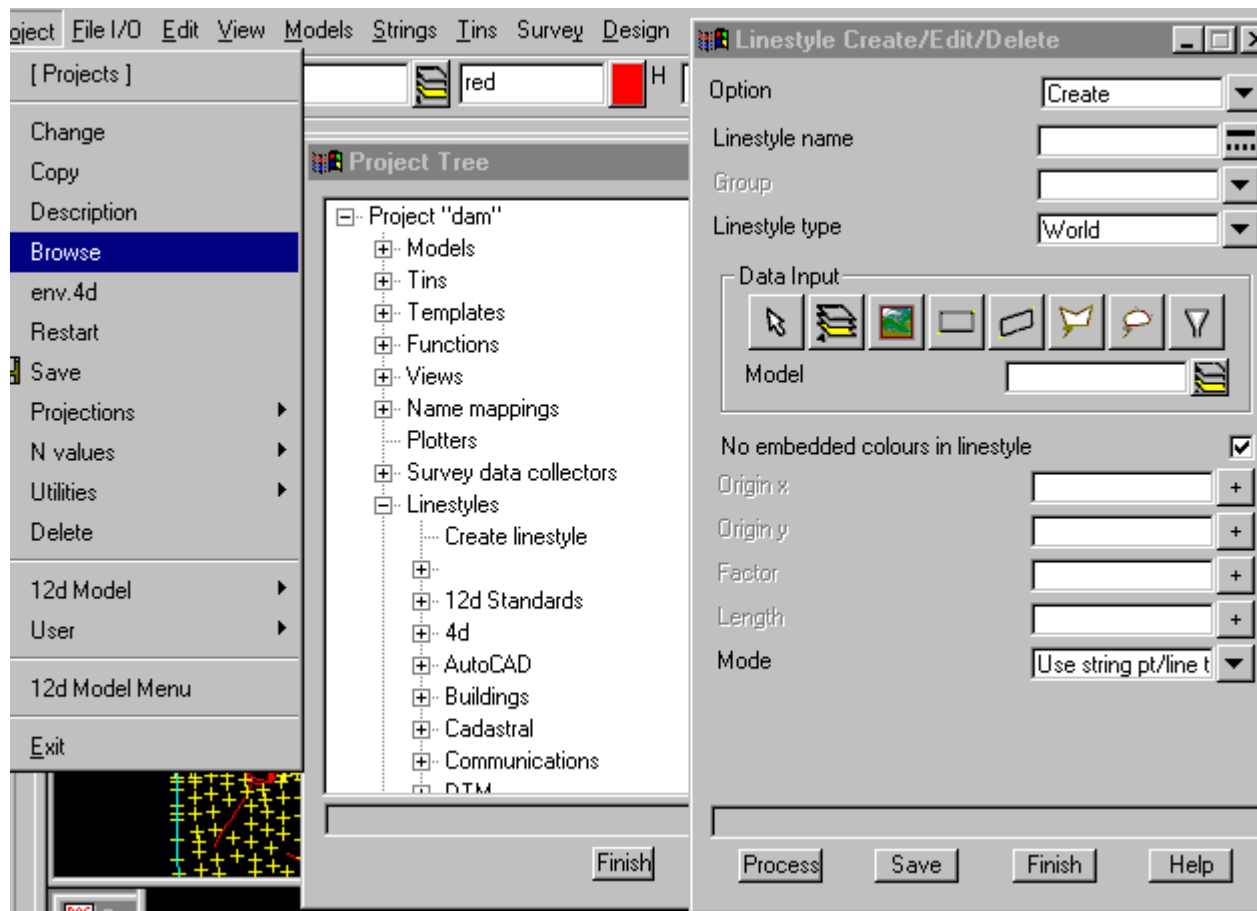

***Note:** In general, if reporting on 12d Model sessions running on a WAN across different time zones, *Local Time of 12d Model User* and *Local Time of 12d_usage User* may be different.

K Line styles, Symbols and Textstyles

Line Styles

Users can define their own line styles to use when drawing 12d Model strings. The definition of linestyles are stored in a file called **linestyl.4d**.

Linestyles in the file can be created/edited/deleted using the **Linestyle Create/Edit/Delete** panel which is brought up by double clicking on *Create linestyle* in the *Linestyles* expansion of the *Project Tree* (see "Linestyles" in the chapter "Projects") brought up by the *Project=>Browse* option.

The **Linestyle Create/Edit/Delete** panel acts as an interactive editor to a text file which contains the linestyle definitions.

The user defined line styles can be

- applied at each vertex of the string - vertex mode
- repeated along the string - continuous mode
- stretched between adjacent vertices of the string
- any combination of the above.

Each line style can be made up of lines, arcs, circles and text.

For cases (a) and (b), the units for the line style can be in pixels, millimetres or world units.

The line style with one origin is called a

linestyle if the definition of the style is given in pixel units

paperstyle if the definition of the style is given in paper units

worldstyle if the definition of the style is given in world units

and line style with two origins is called a **twoptstyle**.

A linestyle, worldstyle or paperstyle can be drawn at each point or repeated along the string.

For case (c) the style is stretched between two adjacent points and is called a **twoptstyle** style.

A twoptstyle stretches between two points in one or both directions.

Finally, case (d) is called a **groupstyle** and is a combined style made up of one or more linestyles, paperstyles, worldstyles or twoptstyles.

A groupstyle made up of a vertex and a continuous line style.

Note:

The words **linestyle** or **line style** are often used in the manual to refer to either a linestyle, paperstyle, worldstyle, twoptstyle or groupstyle.

Defining Line Styles

A *line style* is defined in a (x,y) co-ordinate system as a series of moves, drawn, arcs, circles and text commands.

The bounding box of the line style is the smallest rectangle parallel to the (x,y) axis which contains all the moves, draws, circles and arcs of the line style. Note that moves are included in the bounding box even if a line isn't drawn to the point.

The default **origin of the line style** is defined to be the midpoint of the bounding box surrounding the line style. The bounding box includes the points moved to and drawn to, but does not automatically include (0,0). Hence the calculated origin may not be (0,0).

There are **xorigin** and **yorigin** commands to override the default origin of the line style.

If a **yorigin** is set, then it is used as the y-coordinate of the line style. If the **xorigin** isn't given, then the **xorigin** is the midpoint of the x-extent of the bounding box of the line style.

Similarly, if a **xorigin** is set, then it is used as the x-coordinate of the line style. If the *yorigin* isn't given, then the *yorigin* is the midpoint of the y-extent of the bounding box of the line style.

The default **length** of the line style is the *horizontal size* of the bounding box.

There is a **length** commands to override the default length of the line style. The *length* must always be positive but it can be larger or smaller than the line styles's calculated horizontal length.

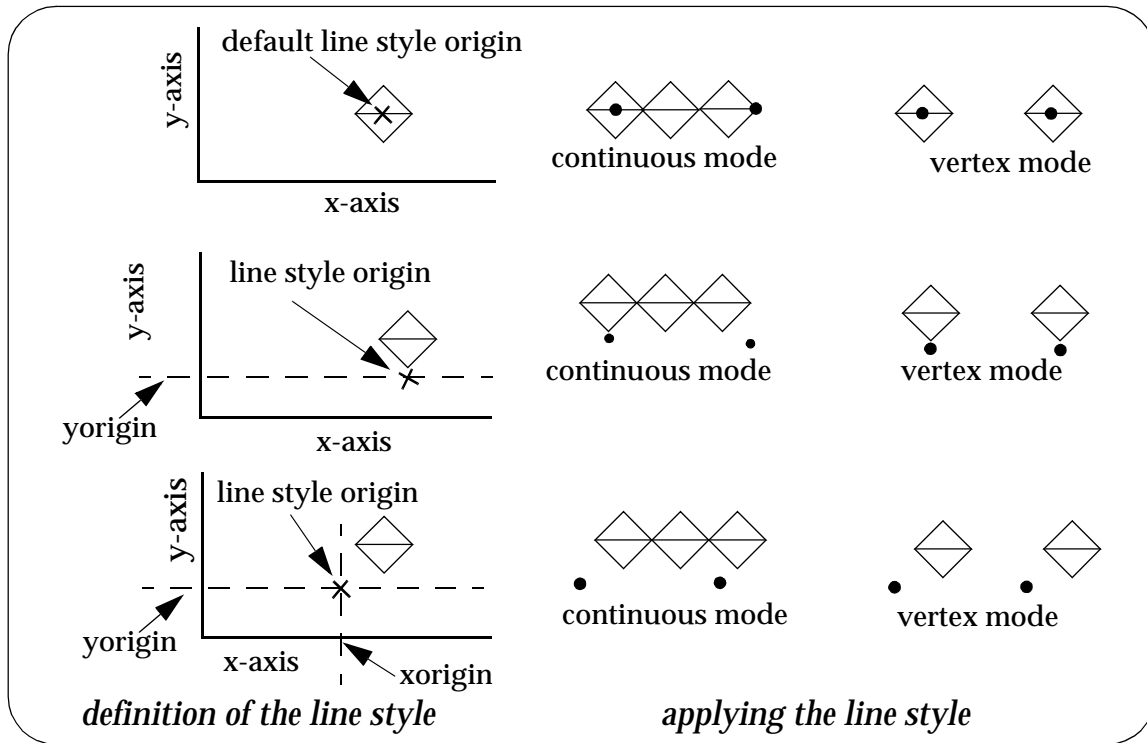

The *origin* and the *length* of the line style are both used in positioning and redrawing the line style.

For *vertex mode*, the **origin** of the line style is placed at each point of the string and the line style drawn around the **origin**.

For *continuous mode*, the **origin** of the line style is initially placed at a distance of half of the **length** of the line style along the first link in the string, and then moved the distance **length** along the string and redrawn. This is repeated along the string until the end of the string is reached.

Hence for *continuous mode*, the style is continually repeated along the string.

Linestyl.4d

The definitions for the available linestyles are normally stored in a file called **linestyl.4d** which is read in each time 12d Model opens an existing project or creates a new project. *Linestyl.4d* is searched for in the standard set up paths, or is pointed to by the environment variable

LINESYLES_4D *filename*

The definition of the line styles will be given in the following section “Line Style Definitions” .

Line Style Definitions

Linestyles, Paperstyles and Worldstyles

The line style with one origin is called a

linestyle if the definition of the style is given in *pixel* units

paperstyle if the definition of the style is given in *paper* units

worldstyle if the definition of the style is given in *world* units

and line style with two origins is called a **twoptstyle**.

The line style can be drawn at each point of a string (**vertex mode**) or redrawn regularly along the lines joining string points (**continuous mode**).

The definition of a **linestyle** of a given name *name* is

```
linestyle name {
  set_up_commands
  draw_commands
}
```

a **paperstyle** is

```
paperstyle name {
  set_up_commands
  draw_commands
}
```

and a **worldstyle** is

```
worldstyle name {
  set_up_commands
  draw_commands
}
```

where the `set_up_commands` **must** be before the `draw_commands`.

The `linestyle`/`paper`/`worldstyle` must have a name and if the name includes imbedded spaces, it must be enclosed in double quotes “”.

The line style itself is defined inside the braces where there can be zero or more `set_up_commands` from the list

```
length    value
group     name
mode      value
factor    value
xorigin   value
yorigin   value
```

followed by zero or more **draw_commands** from the list

```
move      x-value    y-value
draw      x-value    y-value
rmove     dx-value    dy-value
rdraw     dx-value    dy-value
colour    colour_name
circle    radius
arc       radius     start-angle  end-angle
```

```

text      "text"      angle  height  "justification"
text      "text"      angle  height  "justification" "textstyle"
text      "text" angle height "justification" "textstyle" xfactor slant offset_width offset_height
repeat  num_repeats{  repeat_commands repeat_draw_commands}

```

The **repeat** command is a positive integer *num_repeats* and zero or more *repeat_commands* from the list

```

xpos      x-value
ypos      y-value
rfactor   value

```

and zero or more *repeat_draw_commands* where *repeat_draw_commands* include all the *draw_commands* except **repeat**.

The **set_up** commands for linestyles, paperstyles and worldstyles will now be described. The **draw_commands** will be described after the definition of a groupstyle since they are the same for linestyles, paperstyles, worldstyles and twoptstyles.

set_up_commands for Linestyles, Paperstyles and Worldstyles

group

The **group** is used to associate line styles in pop-up menus.

If the group is not defined, the style is placed in a default (blank) group.

If the group name includes imbedded spaces, then it must be enclosed in double quotes " ".

mode

mode specifies whether the linestyle, paperstyle or worldstyle is drawn at the individual points on a string (vertex mode) or it is to be redrawn regularly along the lines joining the points on the string (continuous mode).

If the **mode** is not specified, the mode used for a string depends on the breakline type of the string and the number of points on the string.

Breakline Type	Number of Points	mode: vertex	mode: continuous	mode: not-given
point	1	vertex	cross	vertex
	>1	vertex	continuous	vertex
line	1	vertex	cross	vertex
	>1	vertex	continuous	continuous

NOTE: in early versions of 12d Model, **mode** was known as **pointline** and had the values **point** instead of *vertex*, and **line** instead of *continuous*.

factor

This command factors up/down the drawing co-ordinates, heights and radii.

xorigin, yorigin

The default **origin of the line style** is defined to be the midpoint of the bounding box of the line style. The bounding box includes the points moved to and drawn to but does not automatically include (0,0). Hence the calculated origin may not be (0,0).

The **xorigin** and **yorigin** commands are used to override the default origin of the line style.

length

If **length** is omitted, then **length** is taken to be the horizontal size of the calculated bounding box of the style.

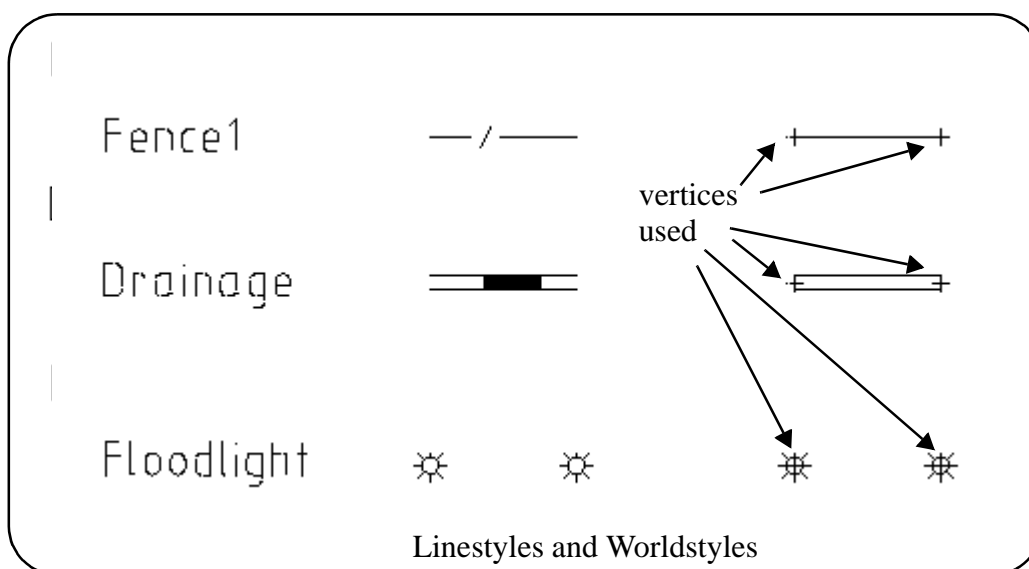

The **length** must always be positive but it can be larger or smaller than the line style's calculated horizontal size.

The origin of the line style and the length are both used in positioning and redrawing the line style.

In **vertex** mode, the origin of the line style is placed at the string points.

In **continuous** mode, the origin is initially placed at a distance of half of **length** along the first line in the string, and then moved the distance **length** along the string for each redraw.

Examples

```
// Fence1
worldstyle "FENCE1" {
  group SWCS
  factor 20
  move 0 0
  rdraw 1 0
  rmove 0.25 -0.25
  rdraw 0.25 0.50
  rmove 0.25 -0.25
  rdraw 1 0
}

// Drainage

worldstyle drainage {
  group "4d"
  factor 0.1
  colour green

  move .0 -2.0 draw 30 -2.0

  move 30 -1.5 draw 15 -1.5
  move 15 -1.0 draw 30 -1.0
  move 30 -0.5 draw 15 -0.5
```

```
    move 15 0.0 draw 30 0.0
    move 30 0.5 draw 15 0.5
    move 15 1.0 draw 30 1.0
    move 30 1.5 draw 15 1.5
    move 30 2.0 draw 0 2.0
}
// Floodlight
worldstyle FLOODLIGHT {
  group "Energex"
  mode vertex
  xorigin 0
  yorigin 0
  colour "yellow"
  circle 0.225
  move -.45 0
  draw -0.225 0
  move .45 0
  draw 0.225 0
  move 0 -.45
  draw 0 -0.225
  move 0 .45
  draw 0 0.225
  move -.159 0.159
  draw -0.318 0.318
  move 0.159 0.159
  draw 0.318 0.318
  move 0.159 -0.159
  draw 0.318 -0.318
  move -0.159 -0.159
  draw -0.318 -0.318
  move 0 0.8
  text "FL" 0 0.5 "centre-middle"
}
```

Twoptstyles

A **twoptstyle** is a line style which is stretched so that one cycle fits between consecutive points on a string (line or arc segments). This is achieved by defining **two origins** for the twoptstyle and the first and second origins are mapped to the consecutive points on the string.

Hence the mapping of the two origins defines the final size of the size in world units.

The *twoptstyle* can stretch in just the direction along the string, or both along and perpendicular to the direction of the string.

Also the *twoptstyle* can be drawn for each line/arc on the string, or for every second line/arc of the string.

For a feature/circle string, the first origin is placed at the centre of the feature/circle and the second origin is placed on the circumference of the feature/circle. Hence the size of the *twoptstyle* is determined by the radius of the feature/circle string.

The definition of a **twoptstyle** of a given name is

```
twoptstyle name {
  set_up_commands
  draw_commands
}
```

where the `set_up_commands` **must** be before the `draw_commands`.

The `twoptstyle` must have a name and if the name includes imbedded spaces, it must be enclosed in double quotes “.

The `twoptstyle` itself is defined inside the braces where there can be zero or more `set_up_commands` from the list

```
group          name
stretch_mode  value
cycle_mode    value
xorigin1      value
yorigin1      value
xorigin2      value
yorigin2      value
```

followed by zero or more `draw_commands` from the list

```
move      x-value  y-value
draw      x-value  y-value
rmove     dx-value  dy-value
rdraw     dx-value  dy-value
colour    colour_name
circle    radius
arc       radius   start-angle  end-angle
text     "text"   angle   height  "justification"
text     "text"   angle   height  "justification"  "textstyle"
text     "text"  angle  height  "justification"  "textstyle"  xfactor  slant  offset  width  offset_height
repeat  num_repeats{  repeat_commands  repeat_draw_commands }
```

The **repeat** command is a positive integer `num_repeats` and zero or more `repeat_commands` from the list

```
xpos      x-value
ypos      y-value
rfactor   value
```

and zero or more `repeat_draw_commands` where `repeat_draw_commands` include all the `draw_commands` except **repeat**.

The `set_up` commands for a `twoptstyle` will now be described. The `draw_commands` will be described after the definition of a **groupstyle** since they are the same for `linestyles`, `paperstyles`, `worldstyles` and `twoptstyles`.

set_up_commands for Twoptstyles

group

The **group** is used to associate line styles in pop-up menus.

If the group is not defined, the line style is placed in a default (blank) group.

If the group name includes imbedded spaces, then it must be enclosed in double quotes “.

stretch_mode

stretch_mode controls whether the symbol stretches in just the direction along the string, or both along and perpendicular to the direction of the string

```
stretch_mode    1          // stretch in one direction only (default)
                 2          // stretch in both directions
```

A twoptstyle stretches between two points in one or both directions.

stretch in one direction

stretch in both directions

cycle_mode

cycle_mode controls whether the symbol is drawn for each line/arc on the string, or for every second line/arc of the string.

cycle_mode

1

// draws on every line/arc (default)

2

// draws every second line/arc

draw on every line/arc

draw on every second line/arc

A twoptstyle draws on each line/arc or every second line/arc

xorigin1, yorigin1

The point (xorigin1, yorigin1) is mapped to the first point that the *twoptstyle* is being applied to.

The default **first point of origin of the twoptstyle** is defined to be the minimum x value and the average of the minimum and maximum y values $(x_{\min}, (y_{\min} + y_{\max}) / 2)$.

The **xorigin1** and **yorigin1** commands are used to override the default first origin of the *twoptstyle*.

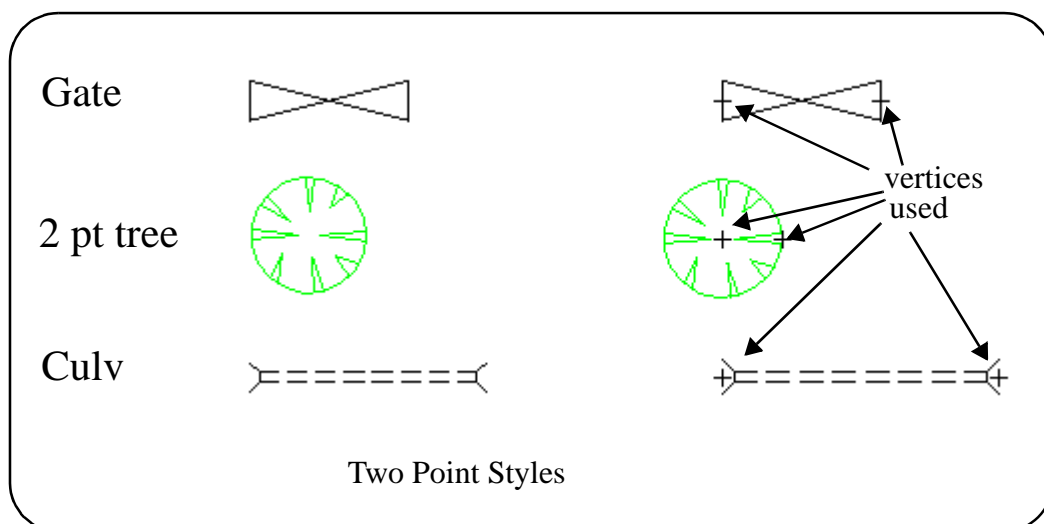

xorigin2, yorigin2

The point (xorigin2, yorigin2) is mapped to the second point that the *twoptstyle* is being applied to.

The default **second point of origin of the twoptstyle** is defined to be the maximum x value and the average of the minimum and maximum y values $(x_{\max}, (y_{\min} + y_{\max}) / 2)$.

The **xorigin2** and **yorigin2** commands are used to override the default second origin of the *twoptstyle*.

Examples

```
// Gate
twoptstyle GATE {
  group "Two Points"
  stretch_mode 2
  cycle_mode 2
  colour red
  move 100 105
  draw 140 95
  draw 140 105
  draw 100 95
  draw 100 105
}
// two point tree
twoptstyle 2PT_TREE {
  group "4d_standards"
  stretch_mode 2
  cycle_mode 2
  xorigin10
  yorigin10
  // xorigin22.5
  // yorigin2 1.25

  colour "green"
  move 0 0
  circle 2.5
  move 2.48 0.2
  draw 0.5 0
  draw 2.48 -0.2
  move 2.2 -1.2
  draw 1.2 -0.9
  draw 1.8 -1.7
  move 0.7 -2.4
  draw 0.2 -1
  draw 0.3 -2.45
  move -0.2 2.45
  draw 0 1
  draw 0.2 2.45
  move 1.2 2.2
```

```
draw 0.9 1.2
draw 1.7 1.8
move -2.48 0.2
draw -0.5 0
draw -2.48 -0.2
move -1.8 1.6
draw -0.8 0.6
draw -2.1 1.3
move -1.6 -1.9
draw -1.1 -0.8
draw -1.3 -2.1
}
// Culvert
twoptstyle CULV {
  group "Two Points"
  stretch_mode 2
  cycle_mode 2

  move 8 12
  draw 10 10
  draw 14 10
  move 16 10
  draw 20 10
  move 22 10
  draw 26 10
  move 28 10
  draw 32 10
  move 34 10
  draw 38 10
  move 40 10
  draw 44 10
  move 46 10
  draw 50 10
  move 52 10
  draw 56 10
  draw 58 12
  move 58 6
  draw 56 8
  draw 56 10
  move 10 10
  draw 10 8
  draw 8 6
  move 10 8
  draw 14 8
  move 16 8
  draw 20 8
  move 22 8
  draw 26 8
  move 28 8
  draw 32 8
  move 34 8
  draw 38 8
  move 40 8
  draw 44 8
  move 46 8
  draw 50 8
  move 52 8
  draw 56 8
```

}

Groupstyles

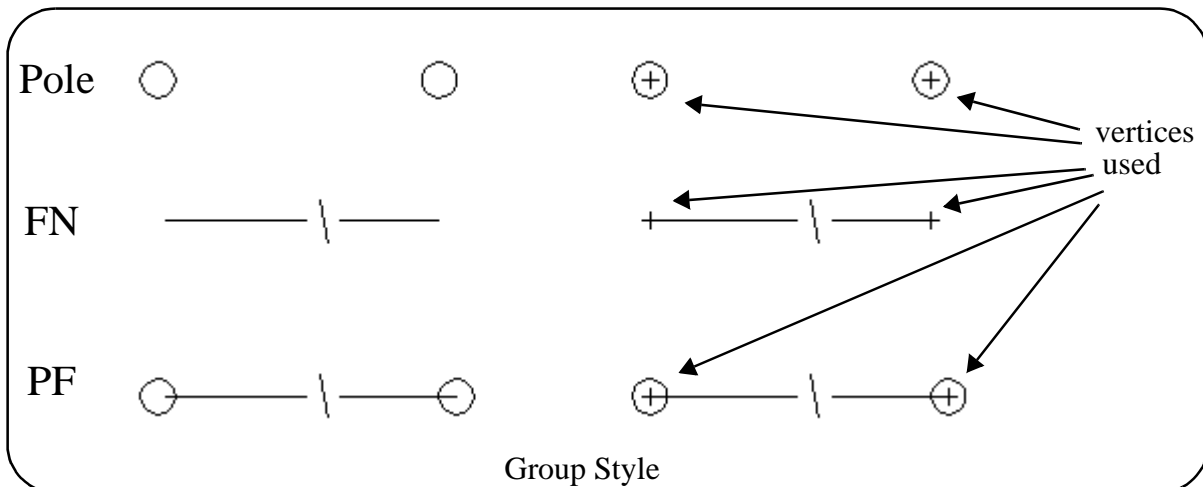

A **groupstyle** is a combined line style which is made up of one or more *linestyles*, *paperstyles*, *worldstyles* and/or *twoptstyles*.

The definition of a **groupstyle** is simply an optional **group** for the line style to belong to, and a list of *linestyle*, *paperstyles*, *worldstyle* and *twoptstyle* names which must have already been defined in the file.

```
groupstyle name {
    group name
    style_name_1
    style_name_2
    ...
}
```

If the *groupstyle* name contains spaces, then it must be enclosed in double quotes ". For example, "style 1".

Example

```
// POLE
worldstyle POLE {
    group "Electricity"
    mode vertex
    circle 0.5
}
// FN
worldstyle FN {
    group "Fences"
    length 5
    draw 4 0
    move 4.4 0.6
    draw 4.6 -0.6
}
// PF
}groupstyle "PF" {
    group "Miscellaneous"
    "POLE"
    "FN"
}
```

Description of the draw_commands

move *x-value* *y-value*

move the pen from the current pen position to the new position (x-value, y-value).

draw *x-value* *y-value*

draw from the current pen position to the new position (x-value, y-value)

rmove *dx-value* *dy-value*

move relative from the current pen position through the distance (dx-value, dy-value)

rdraw *dx-value* *dy-value*

draw relative from the current pen position through the distance (dx-value, dy-value)

colour *colour-name*

change colour (line styles can contains more than one colour).

If colour is not defined, the line style is drawn in the colour of the string that the line style is applied to. If the colour-name includes imbedded spaces, then it must be enclosed within double quotes ".

circle *radius*

draw a circle of the given radius at the current pen position.

After drawing a circle, the current pen position is left at the centre of the circle.

arc *radius* *start-angle* *end-angle*

draw an arc of the given radius from the start angle to the end angle. A positive radius denotes that the arc is drawn in a clockwise direction, a negative radius means anti-clockwise. Angles are given in degrees, minutes and seconds in the ddd.mmssfff format.

After drawing an arc, the current pen position is left at the centre of the arc.

text *text* *angle* *height* "*justification*"

text *text* *angle* *height* "*justification*" *textstyle*

or

text *text* *angle* *height* "*justification*" *textstyle* *xfactor* *slant* *offset_width* *offset_height*

the characters *text* are drawn at the current pen position with the given angle, height, justification and possibly *textstyle*, *xfactor*, *slant*, *offset_width* and *offset_height*. Angle and slant are given in degrees, minutes and seconds in the ddd.mmssfff format. Slant is between -45 and 45 degrees.

The allowed justifications are

top-left	top-centre	top-right
middle-left	middle-centre	middle-right
bottom-left	bottom-centre	bottom-right

and the value is enclosed inside double quotes (").

After drawing text, the current pen position is left where it was before the text was drawn.

repeat num_repeats { *repeat_commands* *repeat_draw_commands* }

The **repeat** command allows the set of *repeat_draw_commands* inside the braces (the *repeat-style*) to be re-drawn a number of times (*num_repeats*), and with each redraw, the size of the *repeat-style* is modified.

In the definition of *repeat*, there can be zero or more *repeat_commands* from the list

xpos *x-value*

ypos *y-value*
rfactor *value*

and zero or repeat_draw_commands where repeat_draw_commands include all draw_commands except **repeat**.

Unlike style, the repeat-style is defined in terms of a local origin at (0,0). The repeat-style is actually drawn with this origin at the position given by the values of **xpos** and **ypos**.

The repeat-style is drawn *num_repeats* times and on each redraw, the distances, heights and radii are factored by the amount

$$\text{repeat_factor} = (1 - i * \text{rfactor})$$

where $i = 0, 1, \dots, \text{num_repeats} - 1$

If rfactor is not specified, it is given the default value of $1/\text{num_repeats}$. The factor is then

$$\text{repeat_factor} = (\text{num_repeats} - i) / \text{num_repeats}$$

where $i = 0, 1, \dots, \text{num_repeats} - 1$

Examples of the Repeat Command

1. To produce circles of radius 10,9,8,...1 about the origin.

```
repeat 10 { circle 10 }
```

2. To produce circles of radius 10,9.5,9,...5.5 about the origin

```
repeat 10 { rfactor 0.05 circle 10 }
```

More Examples of Line, Paper and World Styles

1. draw a circle of radius 20. The origin of the style is (0,0)

```
worldstyle "circle" {  
  move 0 0  
  circle 20  
}
```

2. draw a circle of radius 20. The origin of the style is (100,100)

```
paperstyle "circle" {  
  move 100 100  
  circle 20  
}
```

3. draw a circle of radius 20. The origin of the style is (0,0)

```
linestyle "circle" {  
  xorigin 0  
  yorigin 0  
  move 100 100  
  circle 20  
}
```

4. draw a gate symbol as a twoptstyle.

```
worldstyle "circle" {  
  group "fences"  
  stretch_mode 1                // one direction stretch  
  cycle_mode 2                 // draw every second line  
  
  move 0 0
```

```

draw 0 0.1
draw 1 0
draw 1 0.1
draw 0 0
}

```

5. draw concentric circles of centre (0,0) inside a box

```

linestyle "dot" {
  xorigin 0
  yorigin 0
  move -5 -5
  draw -5 25
  draw 25 25
  draw 25 -5
  draw -5 -5
  repeat 10 {
    move 0 0
    circle 10
  }
}

```

6. draw an arc of absolute radius 10 in the clockwise direction from the angle 45 to the angle -45.

```

linestyle "arc" {
  move 0 0
  arc 10 45 -45
}

```

7. draw an arc of absolute radius 10 in the anti-clockwise direction from the angle 45 to the angle -45.

```

worldstyle "arc 1" {
  move 0 0
  arc -10 45 -45
}

```

8. top-left justified text with a circle centred on the actual text position

```

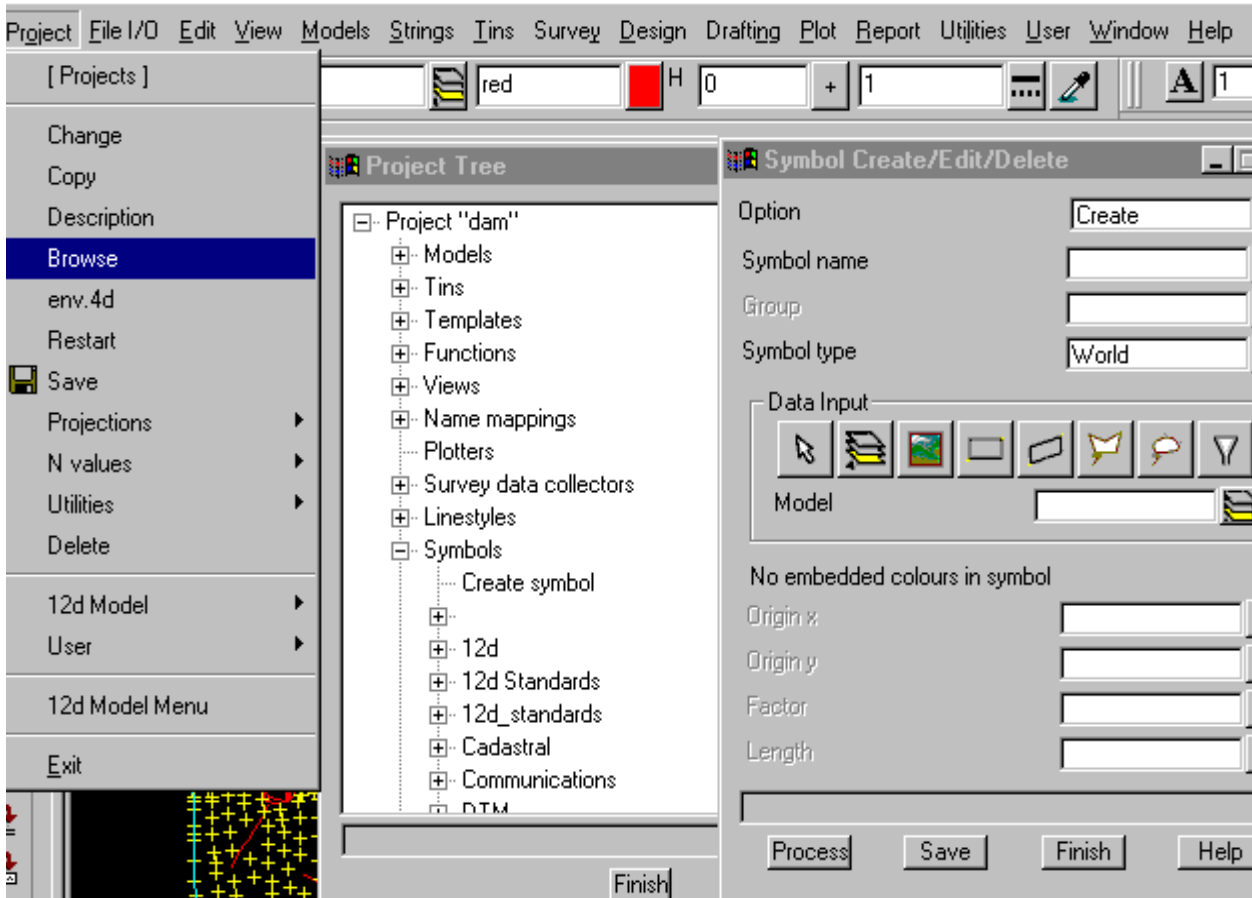

linestyle "top-left" {
  group text
  move 0 0
  circle 4
  text "<top left>" 0 10 "top-left"
}

```

Symbols

Users can define their own symbols to draw at vertices of 12d Model strings. The definition of symbols are stored in a file called **symbols.4d**.

Symbols in the file can be created/edited using the **Symbols Create/Edit/Delete** panel which is brought up by double clicking on *Create symbol* in the *Symbols* expansion of the *Project Tree* (see "Symbols" in the chapter "Projects") brought up by the *Project=>Browse* option.

The **Symbol Create/Edit/Delete** panel acts as an interactive editor to a text file which contains the symbol definitions.

The user defined symbols can be applied to each vertex of a string. Each symbol can be made up of lines, arcs, circles and text.

A symbol applied to vertices.

The units for the symbol can be in pixels, millimetres or world units. The symbol is called a

paperstyle if the definition of the symbol is given in paper units
worldstyle if the definition of the symbol is given in world units

Defining Symbols

A *symbol* is defined in a (x,y) co-ordinate system as a series of moves, drawn, arcs, circles and text commands.

The bounding box of the line style is the smallest rectangle parallel to the (x,y) axis which contains all the moves, draws, circles and arcs of the line style. Note that moves are included in the bounding box even if a line isn't drawn to the point.

The default **origin of the symbol** is defined to be the midpoint of the bounding box surrounding the symbol. The bounding box includes the points moved to and drawn to, but does not automatically include (0,0). Hence the calculated origin may not be (0,0).

There are **xorigin** and **yorigin** commands to override the default origin of the symbol.

If a **yorigin** is set, then it is used as the y-coordinate of the symbol. If the **xorigin** isn't given, then the **xorigin** is the midpoint of the x-extent of the bounding box of the symbol.

Similarly, if a **xorigin** is set, then it is used as the x-coordinate of the symbol. If the **yorigin** isn't given, then the **yorigin** is the midpoint of the y-extent of the bounding box of the symbol.

The default **length** of the line style is the *horizontal size* of the bounding box.

There is a **length** commands to override the default length of the symbol. The *length* must always be positive but it can be larger or smaller than the symbols calculated horizontal length.

The *origin* and the *length* of the symbol are both used in positioning and sizing the symbol.

Symbol.4d

The definitions for the available symbols are normally stored in a file called **symbols.4d** which is read in each time 12d Model opens an existing project or creates a new project. *Symbol.4d* is searched for in the standard set up paths, or is pointed to by the environment variable

SYMBOLS_4D *filename*

The definition of the symbols will be given in the following section “Symbol Definition” .

Symbol Definition

The definition of a worldstyle **symbol** of a given name *name* is

```
worldstyle name {
    set_up_commands
    draw_commands
}
```

where the `set_up_commands` **must** be before the `draw_commands`.

The `linestyle/paper/worldstyle` must have a name and if the name includes imbedded spaces, it must be enclosed in double quotes “.”

The symbol itself is defined inside the braces where there can be zero or more `set_up_commands` from the list

```
length    value
group     name
factor    value
xorigin   value
yorigin   value
```

followed by zero or more **draw_commands** from the list

```
move      x-value    y-value
draw      x-value    y-value
rmove     dx-value    dy-value
rdraw     dx-value    dy-value
colour    colour_name
circle    radius
arc       radius     start-angle end-angle
text      "text"     angle     height    "justification"
text      "text"     angle     height    "justification" "textstyle"
text      "text"    angle     height    "justification" "textstyle" xfactor slant offset_width offset_height
repeat    num_repeats{ repeat_commands repeat_draw_commands }
```

The **repeat** command is a positive integer *num_repeats*

and zero or more `repeat_commands` from the list

```
xpos      x-value
ypos      y-value
rfactor    value
```

and zero or more `repeat_draw_commands` where `repeat_draw_commands` include all the `draw_commands` except **repeat**.

The **set_up** commands for symbols will now be described followed by the **draw_commands**.

set_up_commands for symbols

group

The **group** is used to associate symbols in pop-up menus.

If the group is not defined, the symbol is placed in a default (blank) group.

If the group name includes imbedded spaces, then it must be enclosed in double quotes “.”

factor

This command factors up/down the drawing co-ordinates, heights and radii.

xorigin, yorigin

The default **origin of the symbol** is defined to be the midpoint of the bounding box of the line style. The bounding box includes the points moved to and drawn to but does not automatically include (0,0). Hence the calculated origin may not be (0,0).

The **xorigin** and **yorigin** commands are used to override the default origin of the symbol.

length

If length is omitted, then **length** is taken to be the horizontal size of the calculated bounding box of the symbol.

The **length** must always be positive but it can be larger or smaller than the symbols calculated horizontal size.

The origin of the symbol and the length are both used in positioning and sizing of the symbol.

Examples

```
// Floodlight
worldstyle FLOODLIGHT {
  group "Energex"
  mode vertex
  xorigin 0
  yorigin 0
  colour "yellow"
  circle 0.225
  move -.45 0
  draw -0.225 0
  move .45 0
  draw 0.225 0
  move 0 -.45
  draw 0 -0.225
  move 0 .45
  draw 0 0.225
  move -.159 0.159
  draw -0.318 0.318
  move 0.159 0.159
  draw 0.318 0.318
  move 0.159 -0.159
  draw 0.318 -0.318
  move -0.159 -0.159
  draw -0.318 -0.318
  move 0 0.8
  text "FL" 0 0.5 "centre-middle"
}
```

Description of the draw_commands

move *x-value* *y-value*

move the pen from the current pen position to the new position (x-value, y-value).

draw *x-value* *y-value*

draw from the current pen position to the new position (x-value, y-value)

rmove *dx-value* *dy-value*

move relative from the current pen position through the distance (dx-value, dy-value)

rdraw *dx-value* *dy-value*

draw relative from the current pen position through the distance (dx-value, dy-value)

colour *colour-name*

change colour (line styles can contains more than one colour).

If colour is not defined, the symbol is drawn in the colour of the string that the symbol is applied to. If the colour-name includes imbedded spaces, then it must be enclosed within double quotes ".
.

circle *radius*

draw a circle of the given radius at the current pen position.

After drawing a circle, the current pen position is left at the centre of the circle.

arc *radius* *start-angle* *end-angle*

draw an arc of the given radius from the start angle to the end angle. A positive radius denotes that the arc is drawn in a clockwise direction, a negative radius means anti-clockwise. Angles are given in degrees, minutes and seconds in the ddd.mmssfff format.

After drawing an arc, the current pen position is left at the centre of the arc.

text *text* *angle* *height* "*justification*"

text *text* *angle* *height* "*justification*" *textstyle*

or

text *text* *angle* *height* "*justification*" *textstyle* *xfactor* *slant* *offset_width* *offset_height*

the characters *text* are drawn at the current pen position with the given angle, height, justification and possibly *textstyle*, *xfactor*, *slant*, *offset_width* and *offset_height*. Angle and *slant* are given in degrees, minutes and seconds in the ddd.mmssfff format. *Slant* is between -45 and 45 degrees.

The allowed justifications are

top-left	top-centre	top-right
middle-left	middle-centre	middle-right
bottom-left	bottom-centre	bottom-right

and the value is enclosed inside double quotes (").

After drawing text, the current pen position is left where it was before the text was drawn.

repeat num_repeats { *repeat_commands* *repeat_draw_commands* }

The **repeat** command allows the set of *repeat_draw_commands* inside the braces (the *repeat-style*) to be re-drawn a number of times (*num_repeats*), and with each redraw, the size of the *repeat-style* is modified.

In the definition of *repeat*, there can be zero or more *repeat_commands* from the list

xpos *x-value*

ypos *y-value*

rfactor value

and zero or repeat_draw_commands where repeat_draw_commands include all draw_commands except **repeat**.

Unlike symbol, the repeat-style is defined in terms of a local origin at (0,0). The repeat-style is actually drawn with this origin at the position given by the values of **xpos** and **ypos**.

The repeat-style is drawn *num_repeats* times and on each redraw, the distances, heights and radii are factored by the amount

$$\text{repeat_factor} = (1 - i * \text{rfactor})$$

where $i = 0, 1, \dots, \text{num_repeats} - 1$

If rfactor is not specified, it is given the default value of $1 / \text{num_repeats}$. The factor is then

$$\text{repeat_factor} = (\text{num_repeats} - i) / \text{num_repeats}$$

where $i = 0, 1, \dots, \text{num_repeats} - 1$

Examples of the Repeat Command

1. To produce circles of radius 10,9,8,...1 about the origin.

```
repeat 10 { circle 10}
```
2. To produce circles of radius 10,9.5,9,...5.5 about the origin

```
repeat 10 { rfactor 0.05 circle 10}
```

More Examples of World Styles

1. draw a circle of radius 20. The origin of the style is (0,0)

```
worldstyle "circle" {  
  move 0 0  
  circle 20  
}
```
2. draw a circle of radius 20. The origin of the style is (100,100)

```
worldstyle "circle" {  
  move 100 100  
  circle 20  
}
```
3. draw a circle of radius 20. The origin of the style is (0,0)

```
worldstyle "circle" {  
  xorigin 0  
  yorigin 0  
  move 100 100  
  circle 20  
}
```
4. draw concentric circles of centre (0,0) inside a box

```
worldstyle "dot" {  
  xorigin 0  
  yorigin 0  
  move -5 -5  
  draw -5 25  
  draw 25 25  
  draw 25 -5
```

```
draw -5 -5
repeat 10 {
  move 0 0
  circle 10
}
```

5. draw an arc of absolute radius 10 in the clockwise direction from the angle 45 to the angle -45.

```
worldstyle "arc" {
  move 0 0
  arc 10 45 -45
}
```

6. draw an arc of absolute radius 10 in the anti-clockwise direction from the angle 45 to the angle -45.

```
worldstyle "arc 1" {
  move 0 0
  arc -10 45 -45
}
```

7. top-left justified text with a circle centred on the actual text position

```
worldstyle "top-left" {
  group text
  move 0 0
  circle 4
  text "<top left>" 0 10 "top-left"
}
```

Textstyles and Fonts

Users can define any number of textstyles and specify how they are mapped to AutoCAD style names or Microstation (DGN, Intergraph) font numbers.

There is one fixed spaced textstyle called "1" (the default) which is identical to the textstyle used in earlier versions of 12d Model.

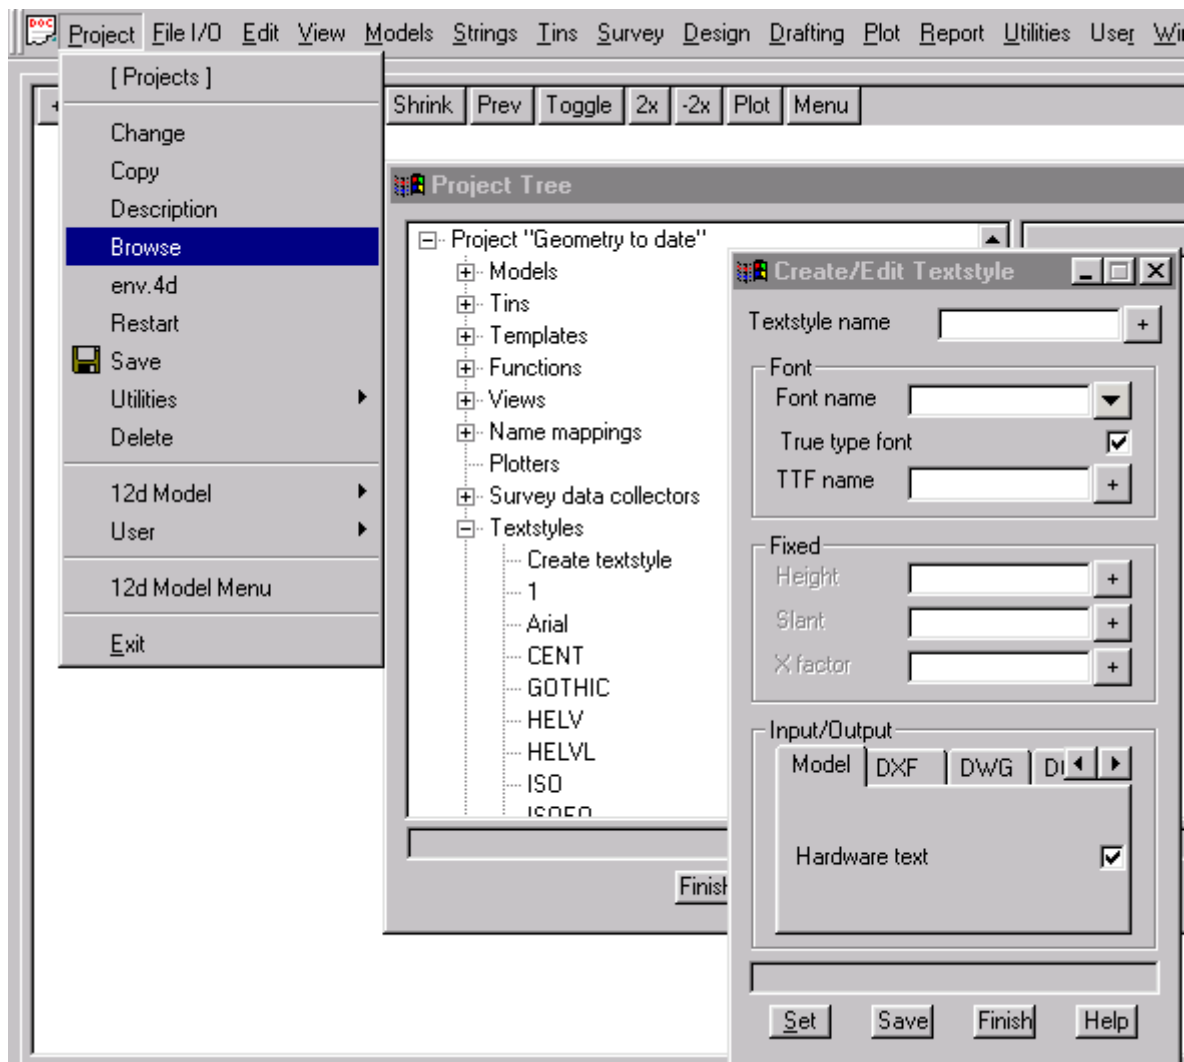

Each textstyle has a font definition (or font 1 as the default) which defines the stroking for each character in the font. True Type fonts are supported and most AutoCAD SHP files can be used to define the fonts.

Textstyles using True Type fonts or shape file which do not use arcs in their font definition, can also have a slant and a x_factor.

Textstyles can be used in text strings, 4d strings, super strings, linstyles, plots and user defined title blocks.

Textstyles Definitions File

Textstyles can be created/edited using the **Create/Edit Textstyle** panel which is brought up by double clicking on *Create textstyle* in the *Textstyles* expansion of the *Project Tree* (see "Textstyles" in the chapter "Projects") brought up by the *Project=>Browse* option.

The **Create/Edit Textstyle** panel acts as an interactive editor to a text file which contains the textstyle definitions. The full description of the text file will now be given.

The definitions for the available textstyles are normally stored in a file called **textstyl.4d** which is read in each time 12d Model opens an existing project or created a new project. *Textstyl.4d* is searched for in the standard set up paths, or is pointed to by the environment variable

```
TEXTSTYLES_4D      filename
```

Inside textstyl.4d, a textstyle of a given name is defined by

```
textstyle textstyle_name {
    textstyle commands
}
```

Each textstyle must have a **name** and if the name includes imbedded spaces, it must be enclosed in double quotes " ".

The textstyle itself is defined inside the braces where there can be zero or textstyle commands from the list

```
font_name          text
or
hardware_text_dxf
stroked_text_dxf
output_name_dxf    text
input_name_dxf     text
or
hardware_text_dgn
stroked_text_dgn
output_name_dgn    integer
input_name_dgn     integer
or
hardware_text_model
stroked_text_model
or
stroked_text
hardware_text
fixed_height       value
variable_height
fixed_slant        value
variable_slant
fixed_xfactor      value
variable_xfactor
```

The description of each command is

```
font_name          text
```

Name of the font to be used to draw the characters of the textstyle. The stroking of the font characters can be defined in the file fonts.4d. If no font_name is given, or the stroking is not given in the font file, then the standard **12d** Model font is used ("1").

```
hardware_text_dxf    or    stroked_text_dxf
```

If stroked_text_dxf appears, then any text in this textstyle written out to dxf will be stroked - that is, broken into straights, lines and curves.

If hardware_text_dxf is in the file, then any text in this textstyle sent to dxf will be given as actual dxf text (not stroked).

output_name_dxf dxf_style_name

If text is sent to dxf as hardware text, the dxf style of the text will be dxf_style_name.

input_name_dxf dxf_style_name

When reading in dxf files, any text of style dxf_style_name will be given the 12d Model textstyle name textstyle_name.

The commands for reading and writing dgn files are similar to those for dxf except that dgn has font numbers.

hardware_text_dgn or **software_text_dgn**

output_name_dgn dgn_font_number

input_name_dgn dgn_font_number

hardware_text_model or **stroked_text_model**

Similarly, when writing out to a 12d Model model. For hardware_text_model, text will be sent to text with the same textstyle.

stroked_text or **hardware_text**

If stroked_text appears in the definition and there is no other hardware_text flag set, then the text will be stroked - that is, broken into straights, lines and curves.

If hardware_text appears in the definition, then the text is written out as hardware text.

By default, the height, slant and xfactor for the text can be set when text is defined however it is possible to set each of height, slant and xfactor to a fixed value.

or **fixed_height** value
variable_height

If fixed_height and a value are specified, then all text in this textstyle is drawn at a fixed height. If fixed_height is missing or variable_height (the default) appears, then each text string in the textstyle has its own height.

or **fixed_slant** value
variable_slant

If fixed_slant and a value are specified, then all text in this textstyle is drawn at a fixed slant. If fixed_slant is missing or variable_slant (the default) appears, then each text string in the textstyle has its own slant. Slant is given in degrees, minutes and seconds in the ddd.mmssfff format and must be between -45 and 45 degrees.

or **fixed_xfactor** value
variable_xfactor

If fixed_xfactor and a value are specified, then all text in this textstyle is drawn at a fixed xfactor. If fixed_xfactor is missing or variable_xfactor (the default) appears, then each text string in the textstyle has its own xfactor.

Example of a Textstyle File

```
textstyle "1" {                    // DGN FONT 0                    ACAD FONT STANDARD
    output_name_dxf                STANDARD
    input_name_dxf                STANDARD
    input_name_dgn                "0"
    output_name_dgn                "0"
    stroked_text
    hardware_text_model
    hardware_text_dgn
    hardware_text_dxf
}
```

```

textstyle ISO {           // DGN FONT 1      ACAD FONT ISO

    font_name            ISO
    input_name_dxf       ISO
    output_name_dxf      ISO
    input_name_dgn       "1"
    output_name_dgn      "1"
    stroked_text
    hardware_text_model
    hardware_text_dgn
    hardware_text_dxf
}

textstyle MONO {         // DGN FONT 2      ACAD FONT MONO

    font_name            MONO
    output_name_dxf      MONOTXT
    input_name_dxf       MONOTXT
    input_name_dgn       "2"
    output_name_dgn      "2"
    stroked_text
    hardware_text_model
    hardware_text_dgn
    hardware_text_dxf
}

textstyle SCRIPT {      // DGN FONT 3      ACAD FONT SCRIPTC

    font_name            SCRIPT
    output_name_dxf      SCRIPTC
    input_name_dxf       SRCIPTC
    input_name_dgn       "3"
    output_name_dgn      "3"
    stroked_text
    hardware_text_model
    hardware_text_dgn
    hardware_text_dxf
}

```

Please see the next section “Fonts Definitions File” for a description of the fonts file.

Fonts Definitions File

The definition of any fonts referred to in the **textstyl.4d** file are given in the **fonts.4d** file which is searched for in the standard **12d** Model set up paths, or is pointed to by the environment variable

```

FONTS_4D      filename

```

The stroking for each character in the font (which is used when drawing the text on the screen and when required, stroking the text for outputs and plots) can be given in a separate file in the Autocad shape file format.

Inside **fonts.4d**, a font of a given name is defined by

```

font    font_name {
        font commands
    }

```

Each font must have a name and if the name includes imbedded spaces, it must be enclosed in

double quotes ".

The font itself is defined inside the braces where there can be zero or more font commands from the list

```
stroke_file      filename
proportional
or               fixed
```

The description of each command is

```
stroke_file      stroke_file_name
```

The name of the file containing the stroking for each character in the font in Autocad ascii shape file format (.shp). The stroke_file_name is searched for in the standard 12d Model set up paths.

If the stroking for a character is not defined, the standard 12d Model character is used instead.

```
proportional      or      fixed
```

If a stroke file is not given, then the font could be a fixed (mono) or proportional font.

Example of a Font File

```
font ISO {
    proportional
    stroke_file "ISO"
}
font GOTHIC {
    proportional
    stroke_file "GOTHICE.SHP"
}
font MONO {
    proportional
    stroke_file "MONOTXT.SHP"
}
```

L Functions Keys, Menus, Toolbars

User Defined Function Keys

The user can define function keys (with possible modifiers) to be used to

- (a) bring up most **12d** Model menus or panels
- (b) toggle certain snaps on or off.
- (c) start some geometry snaps
- (d) read a layout file
- (e) execute a batch file or a program (system call).
- (f) run users **12d** Model macros

The function key definitions are given in the file

userkeys.4d

which is searched for in the standard set up areas (local, USER_4D, user, set_ups etc.) or is pointed to by the environment variable

```
FUNCTION_KEYS_4D          file          // function key definitions
```

The format of the function_keys file is simply a list of function key definitions with only one per lines. Blank lines in the file are ignored and anything on a line after a // is a comment.

The function key definition is

```
MODIFIERS          FUNCTION_KEY          OPERATION
```

where MODIFIERS can be totally missing or any combination of

```
shift
control
or      alt
```

FUNCTION_KEY is one of

```
f1, f2,...f12 (f7 should be avoided since it is used in 12d Model for typed input,
               f1 & f10 should be avoided since they are reserved by Windows NT)
```

and OPERATION is one of

```
menu              menu_name          // raise a menu
panel             panel_name         // raise a panel
snap              toggle_snap        // list of toggle_snaps given below
snap              cogo_snap         // list of cogo_snaps given below
cogo_command      // list of cogo_commands given below
layout            layout_file_name   // run a screen layout file
system            batch_file         // run a batch file
system            program            // run a program
```

or for macros

```
macro      options      user_macro_name      macro_arguments
```

where the macros options are:

```
-no_console      // don't display macro console
-close_on_exit   // remove console when macro terminates
-buttons         // have buttons for finish, restart and quit on console
-allow_defaults  // allow default answers for console questions
```

The default when there are no macro options is to run the macro with a console but without buttons, and to leave the macro console on the screen when the macro terminates.

Menus and Panels

Menus and panels can be programmed by functions keys by simply giving the name of the menu and panel after the menu and panel command respectively.

For example,

```
f5          panel    "String Inquire"
f6          menu     "String Create"
```

View Menus and Panels

Menus and panels for views can be programmed by functions keys by substituting the text \$PLAN_VIEW, \$SECTION_VIEW or \$PERSPECTIVE_VIEW in place of the view name in the panel name or menu name.

For example,

```
f9          panel    "Plan Plot $PLAN_VIEW".
```

A panel for each view type can be programmed for the same modifier and function key combination. If the cursor is over the appropriate view type when the function key is selected, then the panel is fired up.

For example, the three definitions for f5

```
f5          panel    "Section Plot $SECTION_VIEW"
f5          panel    "Plan Plot $PLAN_VIEW"
f5          panel    "Perspective Plot $PERSPECTIVE_VIEW"
```

means that a panel will come up when f5 is selected over any of the three view types.

View Toggle Menus

The **toggle menus** available on each view can be set to a function key by

```
MODIFIERS  FUNCTION_KEY  menu    "Toggle $PLAN_VIEW"
MODIFIERS  FUNCTION_KEY  menu    "Toggle $SECTION_VIEW"
MODIFIERS  FUNCTION_KEY  menu    "Toggle $PERSPECTIVE_VIEW"
```

As for the view menus, the cursor must be over the appropriate view type when the function key is selected.

For example,

```
shift f8 menu "Toggle $PLAN_VIEW"
```

brings up the plan view toggle menu if shift f8 is selected when in a plan view.

Available Snaps to be Toggled

```
toggle_point_snap
toggle_line_snap
toggle_grid_snap
toggle_cursor_snap
toggle_tin_snap
toggle_input_height_snap
toggle_show_information
```

For example,

```
control f2 toggle_point_snap
```

Available Cogo Snaps

```
snap create_edit
snap line_create_edit
snap tangent_items_edit
snap fillet_3_points_edit
```

```

snap fillet_item_item_cp_edit
snap fillet_item_item_radius_cp_edit
snap locate_divide_edit
snap locate_divide_distance_edit
snap parallel_edit
snap intersect_edit
snap intersect_offset_edit
snap bearings_intersect_edit
snap between_points_edit
snap locate_edit
snap locate_chainage_edit
snap locate_offset_edit
snap locate_deflection_edit
snap locate_drop_perpendicular_edit
snap locate_projection_edit
snap locate_two_point_distances_edit

```

For example,

```
shift f1 snap locate_chainage_edit
```

Available Cogo Commands

All the new cogo commands can be activated by a function key.

```

create_edit
line_create_edit
tangent_items_edit
fillet_3_points_edit
fillet_item_item_cp_edit
fillet_item_item_radius_cp_edit
locate_divide_edit
locate_divide_distance_edit
parallel_edit
intersect_edit
intersect_offset_edit
bearings_intersect_edit
between_points_edit
locate_edit
locate_chainage_edit
locate_offset_edit
locate_deflection_edit
locate_drop_perpendicular_edit
locate_projection_edit
locate_two_point_distances_edit

```

For example,

```
f2 between_points_edit
```

Layout Files

Layout files can be called up using the **layout** command.

For example,

```
f8 layout "/temp/contours.slf"
```

System Calls

Programs and batch files can be called up using the **system** command. The directories defined by the environment variables \$LIB_4D and \$USER_4D are included in the PATH environment variables so that any batch files or executables in these areas will be accessible without including any path name in the system call.

For example,

```
f4          system    special.exe    // run the program special.exe
shift f4    system    batch.bat      // run a batch file
control f4  system    "start cmd /k dir" // do a dir in a command shell
```

Macros

User macros can be run and the macros brought up with or without buttons, and with leaving or removing the macro console when the macro has finished.

The macro command structure and options are:

```
macro      options    user_macro_name    macro_arguments
```

where the macros options are:

```
-no_console          // don't display macro console
-close_on_exit       // remove console when macro terminates
-buttons             // have buttons for finish, restart and quit on console
-allow_defaults      // allow default answers for console questions
```

The default when there are no macro options is to run the macro with a console but without buttons, and to leave the macro console on the screen when the macro terminates.

For example,

```
f8  macro -no_console -close_on_exit"/area/drape_align.4do"
f9  macro  -buttons  "/games/lots.4do"
```

For compatibility with earlier versions of 12d Model, the following macro commands are also supported:

```
macro          user_macro_name    // run macro without buttons,
// leave console panel on exit
macro_2        user_macro_name    // run macro without buttons,
// remove console panel on exit
macro_with_buttons user_macro_name // run macro with buttons,
// leave console panel on exit
macro_with_buttons_2 user_macro_name // run macro with buttons,
// remove console panel on exit
```

\$LIB and \$USER_LIB

The variable \$LIB and \$USER_LIB can be used as part of the layout_file_name and user_macro_name to pick up files from either the library or user library.

For example,

```
f7          macro    "$LIB/drape_align.4do"
f8          macro    "$USER_LIB/lots.4do"
f9          layout   "$LIB/contours.slf"
```

Note - if \$LIB_4D is not defined, then 12dmodel/6.00/library is used. If \$USER_LIB_4D is not defined, then 12dmodel/6.00/user_lib is used

Example of a User Function Key File

```
// File to define function key usage
// Note: f1, f6 & f10 are reserved by Windows NT
// f7 is reserved by 4D Solutions for typed input
// Available function key modifiers are
//
//      shift control alt
// Note: some alt key combinations are reserved by Windows NT
// Some sample lines may be
// f5          toggle_point_snap
```

```
// shift f5          toggle_line_snap
// control shift f7  toggle_input_height_snap

// Note that all function key modifiers must come before the function key itself.

// -----

// snaps

f3    toggle_point_snap
f4    toggle_line_snap
f5    toggle_grid_snap
f5    toggle_cursor_snap
f8    toggle_input_height_snap
// snaps cogo

f9    snap intersect_offset_edit
f11   snap locate_chainage_edit
f12   snap locate_drop_perpendicular_edit

// panels

f2    panel "String Inquire"
shift f1 panel "Edit String"
shift f2 panel "String Delete"
shift f3 panel "Clean Model"
shift f4 panel "Delete Model"
shift f5 panel "Strings Edit Ops"
shift f6 panel "Points Edit Ops"
shift f7 panel "String Attributes"
shift f8 panel "Toggle $PLAN_VIEW"

// layout files

control f4 layout "$LIB/tri_contour_clean.slf"

// user macros

control f5 macro -no_console -close_on_exit "$LIB/Culd.4do"

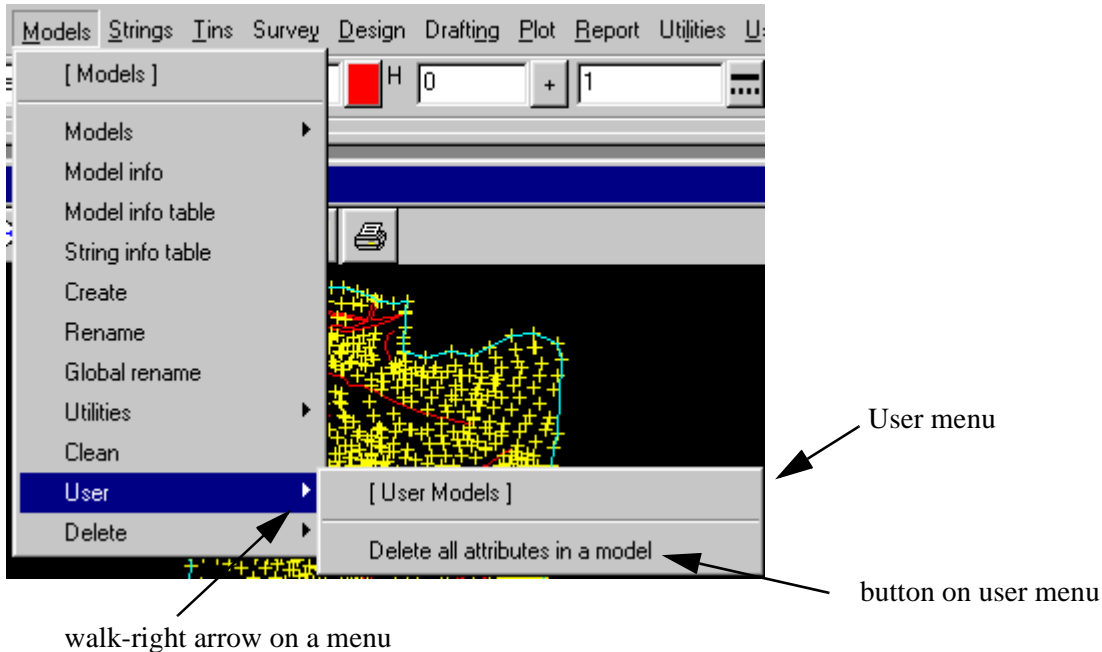

// -----
```

User Defined Menus

To help customise 12d Model, there is a pull down menu **User** on the Main menu and **User** menus on each of the pull down menus on the Main menu.

The **user menus** are made up of *buttons* which have text on them and when the left hand mouse button (LB) is pushed down and released on a button, a *command* is executed.

A button can also have a walk-right menu which appears when the left hand mouse button (LB) is moved over the arrow on the right hand side of the button. Walk-right menus can have walk-right menus.

All the **User** menus can be created by the user and are defined in the file *Usermenu.4d*. Some items on the **User** menus are supplied by 4D Solutions and these are defined in the file *Xtramenu.4d*.

The *text* for each button of **User**, plus the action taken when the button is selected is user specified. Any of the buttons can include further walk-right menus.

When a button is **selected**, the action can be to

- run a 12d Model macro
- bring up a 12d Model menu
- bring up a 12d Model panel
- read a layout file
- execute a batch file or program (system call)

Full Definition of User Menus

The definition for the **User** menus is given in a file called

Usermenu.4d

which is searched for in the standard set up areas (local, USER_4D, user, set_ups etc.) or set by the environment variable

```
USER_OPTIONS_4D          file          // User menu definition
```

In the *Usermenu.4d* file, a menu is defined by:

```
Menu menu_name {
    button_1
    button_2
    ...
    button_n
}
```

where a button can include one or both of the commands *Command* and *Walk_Right*, and the syntax for button is

```
Button button_name {
    Walk_Right          menu_name_1
and/or    Command      command_name
}
```

The *text* displayed on the button is *button_name* and the definitions of the *Walk_Right* and *Command* commands are:

Walk_Right

The *Walk_Right* command specifies that there *is* a walk-right menu for the button and gives the *name* of the menu that is displayed when LB is moved over the walk-right arrow on the button.

The *Walk_Right* command consists of the word *Walk_Right* followed by one or more spaces and then the name of the menu that is displayed when over the walk-right arrow.

```
Walk_Right          menu_name
```

where *menu_name* is the name of another menu defined elsewhere in the *usermenu.4d* file.

When the *Walk_Right* command exists, a walk-right arrow is created on the button. If there is no *Walk_Right* command, then there is no walk right arrow on the button.

The *Walk_Right* command is optional.

NOTE - walk-right menus *can* contain walk-right menus.

Command

The *Command* command defines what action occurs if LB is clicked on the button. The *Command* consists of the word *Command* followed by one or more spaces and then the name of the command and any arguments it requires.

```
Command command_name
```

The Command can bring up any one of

(a) user defined **12d** Model macro

```
Command "macro macro_options user_macro_name macro_parameters" // run macro
```

where the macros options are:

```
-no_console          // don't display macro console
-close_on_exit       // remove console when macro terminates
-buttons             // have buttons for finish, restart and quit on console
-allow_defaults      // allow default answers for console questions
```

The default when there are no macro options is to run the macro with a console but without buttons, and to leave the macro console on the screen when the macro terminates.

- (b) **12d** Model menu
Command "4d_model_menu_name"
- (c) **12d** Model panel
Command "4d_model_panel_name"
- (d) user defined layout file
Command "layout layout_file_name"
- (e) execute a batch file or program
Command "system program_or_batch_file_name"

The *Command* command is optional.

\$LIB and \$USER_LIB

The variable \$LIB and \$USER_LIB can be used as part of the layout_file_name and user_macro_name to pick up files from either the library or user library.

Note - if \$LIB_4D is not defined, then **12d**model/6.00/library is used. If \$USER_LIB_4D is not defined, then **12d**model/6.00/user_lib is used

For example, the definition of a menu called "Lots" could be:

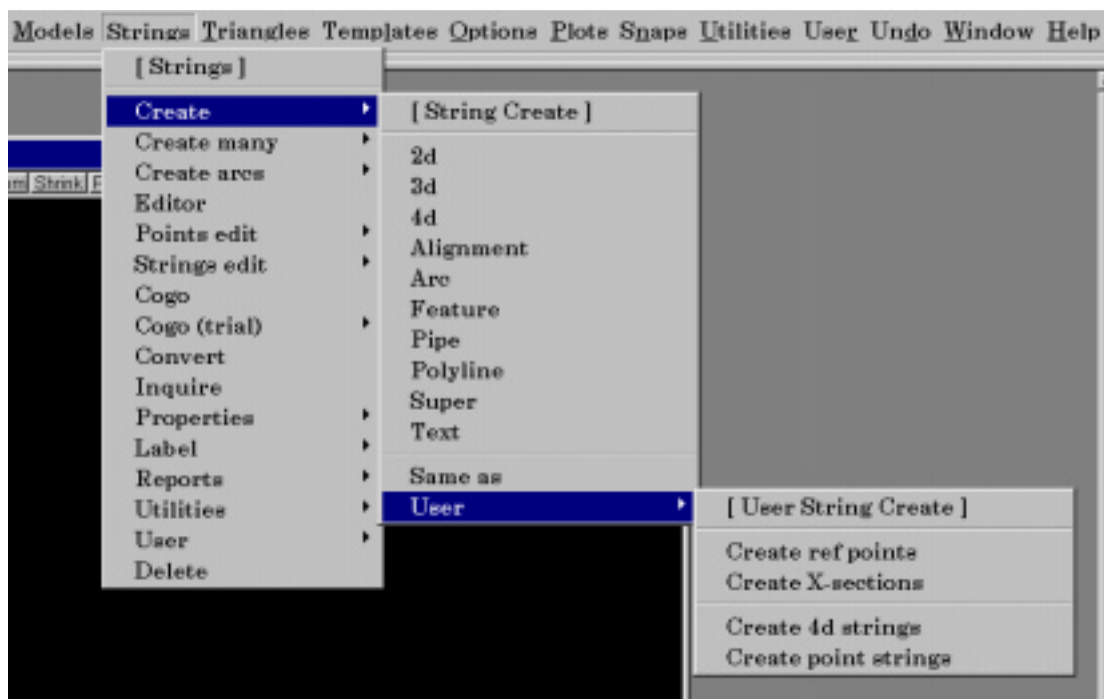

```
Menu "Lots" {
  Button "Create lots" {
    Command "macro -close_on_exit $USER_LIB/subdiv.4do" // fires up a 12d Model macro
  }
  Button "Roads" {
    Walk_Right "Roads" // walk-right menu "Roads"
    Command "layout $USER_LIB/road.slf" // button invokes a layout file if selected
  }
}
```

If a menu called **User** exists in the file, it defines the walk-right menu for **User** on the Main menu.

Since all menus and sub-menus on the **Main** menu have a unique name, it is also possible to defined a **User** menu for any of them by simply having a menu called "User menu_name" in Usermenu.4d.

For example, the menu for the option *Strings=>Create* is called **String Create** (String not Strings) so the User menu for *Strings=>Create* would be called "User String Create":

```
Menu "User String Create" {
  Button "Create 4d strings" {
    Command "macro -close_on_exit $USER_LIB/ref_points.4do"
  }
  Button "Create point strings" {
    Command "macro -close_on_exit $USER_LIB/x_sects.4do"
  }
}
```

All other menu names in Usermenu.4d are user specified and can be used to define walk-right menus.

Any menu referred to in the file Usermenu.4d must be either the name of a standard 12d Model menu, a User menu or must be defined *somewhere in the file*.

Notes

- The variables \$LIB and \$USER_LIB can be used as part of the layout_file_name and user_macro_name to pick up files from either of the libraries.
- blank lines are ignored and anything on a line after a // is a comment

Example of a User Defined Menu

```
// the definition of Main menu option "User"
Menu "User" {
  Button "Triangulate" {
    Command "Triangulate a View"
  }
  Button "Lots" {
    Walk_Right "Lots"
  }
  Button "Roads" {
    Walk_Right "Roads"
    Command "layout $LIB/road.slf"
  }
}

// the definition of the walk-right menu Lots
Menu "Lots" {
  Button "Create lots" {
    Command "macro $LIB/subdiv9.4do"
  }
  Button "Label lots" {
    Command "macro $LIB/subnum3.4do"
  }
}
```

```
    Button "Write Lot Levels" {
      Command "macro $LIB/Tinval.4do"
    }
  }

// the definition of the walk-right menu Roads

Menu "Roads" {
  Button "Roundabout" {
    Command "macro $LIB/Round.4do"
  }
  Button "Culdesac bulb" {
    Command "macro $LIB/Culd.4do"
  }
  Button "Drape alignment string" {
    Command "macro $LIB/Drape_al.4do"
  }
  Button "Create Table drain" {
    Command "macro $LIB/Table_dr.4do"
  }
}

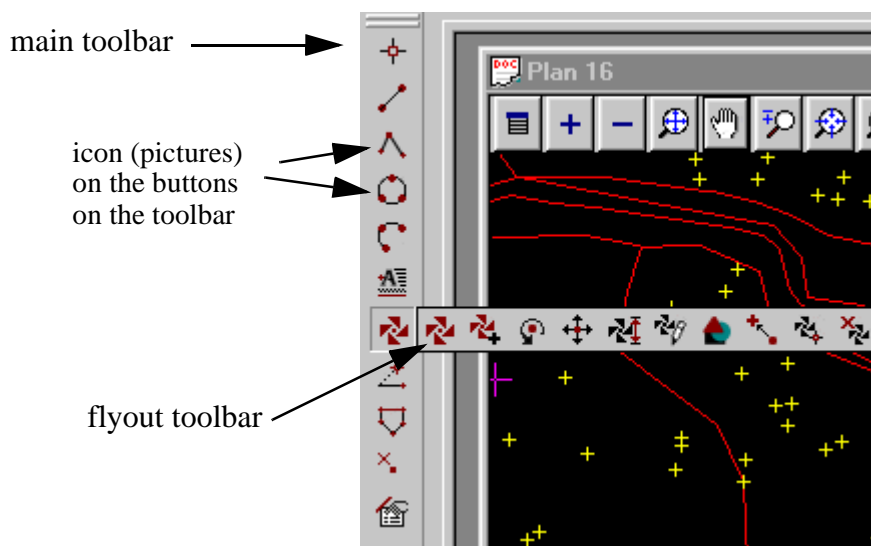

// the definition of User on the Main menu option Strings=>Create"

Menu "User String Create" { // User menu on option Strings=>Create
  Button "Create ref points" {
    Command "macro -close_on_exit $LIB/ref_points.4do"
  }
  Button "Create X-sections" {
    Command "macro -close_on_exit $LIB/x-Sects.4do"
  }
}
}
```

User Defined Toolbars

A *toolbar* is made up of buttons which can have a picture on them (icons) and when the left hand mouse button (LB) is pushed down and released on the button, a command is executed.

A button can also have a *flyout* toolbar which appears when the left hand mouse button (LB) is held down on the button (note that there can only be one level of flyouts).

The definitions for *toolbars* in 12d Model are stored in a file called *toolbars.4d*. When 12d Model is installed, *toolbars.4d* is installed in the 12d Model folder *Set_Ups*.

To customise 12d Model toolbars, a user can modify *toolbars.4d* and save the modified version in the folder *Users*.

The icon for each button on a toolbar, plus the action taken when the button is selected is user specified. A button can include a fly-out toolbar but flyouts can only be to one level (i.e. no flyouts on flyouts).

When a button is **selected**, the action can be to

- run a 12d Model macro
- bring up a 12d Model menu
- bring up a 12d Model panel
- read a layout file
- execute a batch file or program (system call)

When 12d Model starts up, any toolbars defined in *toolbars.4d* that are *not* called as flyouts by another toolbar in *toolbars.4d*, are displayed in the *main toolbar* on the left hand side of the 12d Model screen.

For 12d Model V6.0, toolbars can be moved around but the new positions are not saved with the project. Also there is no way within 12d Model to select which toolbars are used for a project - all the ones defined in *toolbars.4d* are used whenever a new or existing project is loaded into 12d Model V6.0.

Full Definition of Toolbars

The definition for **Toolbars** is given in a file called

Toolbars.4d

which is searched for in the standard set up areas (local, USER_4D, user, set_ups etc.) or set by the environment variable

```
TOOLBARS_4D           file           // Toolbars definition
```

In the *toolbars.4d* file, a *toolbar* is defined by:

```
Toolbar toolbar_name {
    button_1
    button_2
    ...
    button_n
}
```

where a button can include none or more the commands *Icon*, *Command* and *Flyout*, and the syntax for button is:

```
Button button_name {
    Icon      icon_name_1
    Command   command_name_1
    Flyout    toolbar_name_1      // only used if a flyout toolbar is required
}
```

The definitions of the *Icon*, *Command* and *Flyout* commands are:

Icon

The *Icon* command defines the bitmap that is displayed for the button in the toolbar. The format of the bitmap is a bmp file (.bmp) of size 16x16. The *Icon* command consists of the word *Icon* followed by one or more spaces and then the name of the bitmap, *icon_name*.

```
Icon icon_name
```

The *icon_name* can include a pathname but if no pathname is present, the bitmap is searched for in the folder *Images* under the folders *User* or *Set_Ups*.

If the *Icon* command is missing then a default *Icon* command is used with the *icon_name* *button_name.bmp*

```
Icon button_name.bmp
```

Command

The *Command* command defines what action occurs if LB is clicked on the button. The *Command* command consists of the word *Command* followed by one or more spaces and then the name of the command and any arguments it requires.

```
Command command_name
```

The Command can bring up any one of

- (a) user defined 12d Model macro

```
Command "macro macro_options user_macro_name macro_parameters" // run macro
```

where the macros options are:

```
-no_console           // don't display macro console
-close_on_exit       // remove console when macro terminates
-buttons             // have buttons for finish, restart and quit on console
-allow_defaults     // allow default answers for console questions
```

The default when there are no macro options is to run the macro with a console but without buttons, and to leave the macro console on the screen when the macro terminates.

- (b) 12d Model menu

```
Command "4d_model_menu_name"
```

- (c) 12d Model panel

Command "4d_model_panel_name"

(d) user defined layout file

Command "layout layout_file_name"

(e) execute a batch file or program

Command "system program_or_batch_file_name"

If the *Command* command is missing then a default *Command* is used with the command name *button_name* with no arguments

Command *button_name*

Flyout

The *Flyout* command defines what toolbar is displayed when LB is help down on the button. The *Flyout* command consists of the word *Flyout* followed by one or more spaces and then the name of the toolbar that is displayed.

Flyout *flyout_toolbar_name*

where *flyout_toolbar_name* is the name of another toolbar defined elsewhere in the toolbars file.

When the *Flyout* command exists, *Icon* and *Command* are not required and if they are present, are ignored.

The icon on the *Flyout* button is the *Icon* from the first button in the flyout toolbar.

The command executed if LB is pressed and released on the *Flyout* button is the *Command* from the first button in the flyout toolbar.

NOTE - flyouts *can not* be nested so the toolbar *flyout_toolbar_name* can not contain a *Flyout* command.

NOTE - when **12d** Model starts up, any toolbars defined in *toolbars.4d* that are *not* called as flyouts by another toolbar in *toolbars.4d*, are displayed in the *main toolbar* on the left hand side of the 12d Model screen.

Example of a User Defined Toolbar

```
// -----
// WARNING: you cannot have the same command using different icons
// ALSO: when using a flyout, the Command & Icon are ignored
//   and the details are taken from the first button
//   on the flyout
// -----
Toolbar "Cad" {
  Button "Points" {
    Command "Create Point"           // this is ignore since it is a flyout
    Icon  "Create Point.bmp"        // this is ignore since it is a flyout
    Flyout "Cad Points"
  }
  Button "Change String" {
    Flyout "Change String"
  }
}

Toolbar "Cad Points" {              // used as a flyout toolbar
  Button "Create Point" {
    Command "Create Point"
    Icon  "Create Point.bmp"
  }
  Button "Chainage" {
    Command "Locate Chainage"
    Icon  "Chainage.bmp"
  }
}
```

```
} // end of "Cad Points" toolbar

Toolbar "Change String" {                               // used as a flyout toolbar
  Button "String Close" {
    Command "String Close"
    Icon "String Close.bmp"
  }
  Button "String Reverse" {
    Command "String Reverse"
    Icon "String Reverse.bmp"
  }
  Button "String Trim" {
    Command "String Trim"
    Icon "String Trim.bmp"
  }
} // end of "Change String" toolbar
```

\$LIB and \$USER_LIB

The variable \$LIB and \$USER_LIB can be used as part of the layout_file_name and user_macro_name to pick up files from either the library or user library.

Note - if \$LIB_4D is not defined, then 12dmodel/6.00/library is used. If \$USER_LIB_4D is not defined, then 12dmodel/6.00/user_lib is used

For example, the definition of a toolbar called "Lots" could be:

```
Toolbar "Lots" {
  Button "Create lots" {                                // button called "Create lots" which
    Command "macro -close_on_exit $USER_LIB/subdiv.4do" // fires up a 12d Model macro
  }
  Button "Roads" {                                     // button with walk-right menu "Roads" and layout file
    Walk_Right "Roads"                                // walk-right menu "Roads"
    Command "layout $USER_LIB/road.slf"                // button invokes a layout file if selected
  }
}
```

Notes

- (a) The variables \$LIB and \$USER_LIB can be used as part of the layout_file_name and user_macro_name to pick up files from either of the libraries.
- (b) blank lines in the toolbars file are ignored and anything on a line after a // is a comment

Another Example of a Toolbar

```
Toolbar "Cogo" {
// in this case, the Command is assumed to be "Create Line"
// the icon is "Create Line.bmp"
// Command is normally the name of the panel/menu
  Button "Create Line" {
  }
// this is a spacer
  Button "" {
  }
}
```

```
// this is a command and also has a flyout capability
// calling the toolbar called Flyout
// flyouts cannot be nested
Button "Create Fillet by radius" {
  Command "Create Fillet by radius"
  Icon "Create Fillet by radius.bmp"
  Flyout "Flyout"
}
}
// The flyout toolbar for above (and a normal toolbar as well)
Toolbar "Flyout" {
  Button "Create Line" {
  }
  Button "" {
  }
  Button "Create Arc by Centre Radius" {
    Command "Create Arc by Centre Radius End Points"
    Icon "Create Arc by Centre Radius End Points.bmp"
  }
  Button "Create Fillet by radius" {
    Command "Create Fillet by radius"
    Icon "Create Fillet by radius.bmp"
  }
}
```

M Special File Formats

Default File Ending

In any panel pop-up requiring a file name to be displayed, default file endings are used to restrict the **names** of the files selected from the current folder and if they exist, from the library and user library areas.

Whilst a panel is up, the extension being searched for can be changed by typing say "*.xyz" into the panel field requiring a file name, and then pressing <enter>. The list of files ending in .xyz will be displayed and clicking B3 in the panel field will also bring up a list of all files ending in ".xyz". When a new panel is created, the panel fields revert to the default file ending.

A full list of the **default** files used in **12d** Model pop-ups and their endings is:

File Type	Default Ending
------------------	-----------------------

macro source file	.4dm
macro object/executable	.4do
macro listing	.4dl

Note

This list is for the default files used in 12d Model panel fields. It does not include 12d Model setup files which are given in the Appendix **Set Ups**.

Special 12D Solutions File Formats

12D Solutions has a number of special file formats, most of which have already been specified. The remaining formats will now be given.

In any of the files, blank lines ignored and any information after // until the end of that line is ignored. Hence **comments** can easily be inserted into the files by preceding them by //.

Unless enclosed in quotes ("), more than one consecutive space or tab are treated as one space.

Eagle Map File

An eagle map file is a user created file consisting of a list of **12d** Model colours and the Eagle pen, dash style, pen thickness and frag to be used for the colour.

The map file is set out with one **12d** Model colour per line. The line begins with the **12d** Model colour followed by the Eagle pen number, dash style, thickness and frag to be used for the **12d** Model colour. Each item is separated by one or more spaces.

For example, if the **12d** Model colour **red** is to be mapped to Eagle pen 3, dash style 4, thickness 2 and frag 1, then the line in the eagle map file would be

```
red      3      4      2      1
```

An eagle map file can be used for writing out three dimensional data to Eagle, or when producing plots in Eagle format.

For plotting, the map file must be called **eagleplt.emf**.

When writing three dimensional data out to Eagle, a user specified file name is allowed.

In the output case, as each string is written out, the map file is searched sequentially until a colour match is made. If no match is found, the colour of the string is used as a pen number and default values used for dash, thickness and frag.

Comments can be included in the map file by preceding the comment with a double forward slash (i.e. //). Anything on the line following the // will be ignored.

An example of an Eagle map file is,

```
//12d Model colour to Eagle mapping file
//
//12d Model colour eagle pen      dash  thickness  frag

black      0      1      1      1
red        2      0      1      5
green      4      1      1      1
blue       4      2      1      11
cyan       5      1      1      1
yellow     6      1      1      1
magenta    7      1      1      1
white      1      1      1      1
orange     15     1      1      1
purple     14     1      1      1
grey       13     1      1      1
"dark green" 12     1      1      1
"dark red"  11     1      1      1
"off yellow" 4      1      1      1
"dark blue" 8      1      1      1
brown      11     1      1      1
```

Template File

The 12D Solutions Template file format is a simple ascii file definition for reading and writing out template definitions for use in the apply options in 12d Model.

The template definition begins with the key word **template** followed by the template name and then the definitions of

fixed, cut, fill and final parts of the template
 or
 fixed and decision parts
 all enclosed within curly braces { }.

```

template fred {
    fixed {
        ...
    }
    cut {
        ...
    }
    fill {
        ...
    }
    final {
        ...
    }
}

```

or

```

template fred {
    fixed {
        ...
    }
    decisional {
        ...
    }
}

```

The definition of the **fixed** part of the template begins with the key word **fixed** followed by a list of the links enclosed in curly braces {}.

The links are defined one per line in order from the centre-line. Each link begins with the keyword **link** followed by the width, percent cross-fall, colour and name for each link. For the percent cross-fall, positive means up, negative is down and zero horizontal.

For example,

```

fixed {
    link    3.5    -3    cyan    kerb
    link    1      -4    magenta shoulder
    link    2      -5    blue    verge
}

```

describes a fixed template with three links, the first of width 3.5 with a 3% cross-fall downwards, the next link of width 1 with 4% cross-fall downwards and the third link of width 2 and 5% cross-fall downwards.

The definition of the **cut** part of the template begins with the key word **cut** followed by a list of the links enclosed in curly braces {}.

The links are defined one per line in order from the end of the fixed template (or centre-line if no fixed part exists). Each link begins with the keyword **link** followed by the width, one in slope, colour and name for each link. For cut, the **one in** slope is positive for up, negative for down, and zero for horizontal.

For example,

```
cut {
  link 3      2      yellow a
  link 2      0      magenta b
  link 3     -1      yellow c
  link 2      0      magenta d
}
```

describes a cut template with four links, the first of width 3 with 1:2 slope upwards, the next link of width 2 horizontally, the third link of width 3 and 1:1 slope downwards and width 2 horizontally.

The definition of the **fill** part of the template begins with the key word **fill** followed by a list of the links enclosed in curly braces {}.

The links are defined one per line in order from the end of the fixed template (or centre-line if no fixed part exists). Each link begins with the keyword **link** followed by the width, one in slope, colour and name for each link. For fill, the **one in** slope is positive for down, negative for up, and zero for horizontal. Please note that this is the opposite to **cut**.

For example,

```
fill {
  link 5      2      yellow e
  link 1      0      magenta f
  link 10     -1      yellow g
}
```

describes a fill template with three links, the first of width 5 with 1:2 slope downwards, the next link of width 1 horizontally, and the third link of width 10 and 1:1 slope upwards.

The definition of the **final** part of the template begins with the key word **final** followed the cut slope, fill slope and search distance enclosed in curly braces {}. The key words for the three values are `cut_slope`, `fill_slope` and `search_distance`.

For example,

```
final {
  cut_slope 1 fill_slope 2 search_distance 100
}
```

describes a final cut slope of 1:1 (upwards), fill slope of 1:2 downwards and template with three links, the first of width 5 with 1:2 slope downwards, both going for a maximum distance of 100.

The definition of the **decisions** part of the template begins with the key word **decisional** followed by a list of the decision commands enclosed in curly braces {}.

The decision commands are defined one per line and have the format:

Fixed Xfall *Width value Height value XFall value Name text Colour colour*

Fixed Slope *Width value Height value Slope value Name text Colour colour*

Tin Width *tin_name Strip value width value Name text Colour colour*

String Offset *string_name Strip value Offset value Name text Colour colour*

Batter *tin_name Strip value Width value Height value Slope value Name text
Colour colour Goto label*

Tin Decision *tin_name Offset value Min value Max value Goto label*

Label *label_name*

Goto *label_name*

End

For example,

```
template "std" {
  fixed {
    link 3 unknown -3 cyan "kerb"
    link 1 unknown -4 magenta "shoulder"
    link 2 unknown -5 purple "verge"
  }
  decisional {
    Tin_Decision "rock" 0 0 1000 "cut_rock"
    Tin_Decision "shale" 0 0 1000 "cut_shale"
    Tin_Decision "terrain" 0 0 1000 "cut_terrain"
    Label "fill_terrain"
    Batter "terrain" 0 8 unknown -3 "f1" blue "alldone"
    Batter "terrain" 0 1 unknown 0 "f2" "dark green" "alldone"
    Goto "fill_terrain"
    Label "cut_rock"
    Tin_Decision "rock" 0 0 0.3 "cut_rock_done"
    Batter "rock" 0.3 5 unknown 0.5 "r1" cyan "cut_rock_done"
    Batter "rock" 0 2.5 unknown 0 "r2" yellow "cut_rock_done"
    Goto "cut_rock"
    Label "cut_rock_done"
    Tin_Decision "shale" 0 0 1000 "cut_shale"
    Goto "cut_shale_done"
    Label "cut_shale"
    Tin_Decision "shale" 0 0 0.6 "cut_shale_done"
    Batter "shale" 0.6 6 unknown 1 "s1" magenta "cut_shale_done"
    Batter "shale" 0 3 unknown 0 "s2" "dark red" "cut_shale_done"
    Goto "cut_shale"
    Label "cut_shale_done"
    Tin_Decision "terrain" 0 0 1000 "cut_terrain"
    Goto "alldone"
    Label "cut_terrain"
    Batter "terrain" 0 3 unknown 1.5 "t1" red "alldone"
    Batter "terrain" 0 2 unknown 0 "t2" green "alldone"
    Goto "cut_terrain"
    Label "alldone"
  }
}
```

Notes

- spaces in text - any text string that includes spaces or only numbers, must be enclosed in double quotes "
- comments - anything after // until the end of the line is ignored.
- blank lines - blank lines are ignored

Screen Layout File

The **12d Model screen layout file** is a simple text file definition for reading and writing out the information about **12d Model** panels and menus.

The definition includes a screen position for the panel or menu, and for panels, the values for any of the panel fields.

At any time, the layout of the menus and panels on the screen in a **12d Model** session can be written out using the menu option

File i/o=>Layout output.

Also, the layout for an individual panel or menu can be created by clicking RB in the menu/view title area and selecting the dump option to bring up the **Menu/Panel Dump** panel.

An example of a screen layout file is:

```

Panel "Read x y z s Data" {
  Position      116  187
  Field "File"          "faces.dat"
  Field "Map file"      ""
  Field "Prefix for models" ""
  Field "Default line colour" "magenta"
  Field "Default point colour" "yellow"
  Field "Default model for data" "faces"
  Field "Add to view"    "1"
}
Panel "Triangulate a Model" {
  Position 397 187
  Field "Model to triangulate" "faces"
  Field "New tin name" "faces"
  Field "Tin colour" "green"
  Field "Tin style" "1"
  Field "Model for tin" "tin faces,1,2"
  Field "Preserve strings" "true"
  Field "Weed tin" "true"
  Field "Remove bubbles" "true" // for a tick-cross box
                                //case sensitive
  Field "Face data" "true" // true, false, yes,
                                // no, 0 ,1
  Run "Triangulate"
}
Menu "Triangles" {
  Position 300 400
}

```

Map File for 12d Model V4.0

Up to 12d Model V4.0, the map file format consisted of one or more lines. Each line begins with a key (entity-mask) followed by a string name, model name, colour, breakline type (point or line), and line style separated by one or more spaces. The key can contain wild cards (*) and wild

characters (?).

When a string is read in and satisfies a key, the key's corresponding string name, model, colour, breakline type and style is used for that string.

For example, any entity name beginning with **31** can be created as a **12d** Model string with the name **picket**, colour **cyan**, breakline type **line**, line style **1** and model **fences** by the map file line

```
31*      picket      fences      cyan      line      1
```

If a map file is used, as each entity is read in, the map file is searched **sequentially** until a match with a key is made and the key's name, colour etc. used. If no match is found, the default colours and model (given in the read panel) are used.

Notes

1. If the entity-name is to be used as the new string name, use an asterisk (*) in place of the string name. For example,

```
fred      *      fences      cyan      line      1
```
2. If the default model for the reader is to be used as the model name, use an asterisk in place of the model name. For example,

```
31      31      *      cyan      line      1
```
3. A * for colour, breakline type and linestyle means that if the entity has a colour, breakline style or linestyle, then it is used rather than be mapped to another one.
4. All model names used in the map file can be given an extra (common) prefix by typing the prefix into the prefix for models field in the read panel.
5. If any information includes a space, then it must be enclosed in quotes ". For example, the model name may be "trial 1" or a style "large tanks".
6. Comments can be included in the map file by preceding them with a double forward slash //. Anything on the line after the // is ignored.

An example of a **12d** Model map file is

```
// 12d Model map file
// key      name      model      colour      pt-line      linestyle

102      break      breaks      red      line      solid
305      fence      caddast      green      point      dash
998      bdry      bound      cyan      line      solid
spots      *      spot      yellow      point      1
PS*      *      *      yellow      point      1
```

Map File for 12d Model V5.0 and Above

For 12d Model V5.0, the map file was extended to allow for defining properties such as tinability, symbols at vertices, vertex and segment text and pipe and culverts.

To allow for all the different type of mapping in the one file, the map file is broken up into sections (one section for each tab of the map file editor) and each section begins with a header record which is the section name enclosed in braces ({}). For example, the symbols section has the header

```
{symbol_data}
```

Inside each section, the data is similar to the V4.0 map file with lines consisting of a key (entity-

mask) followed by the data required for that section. The key can contain wild cards (*) and wild characters (?).

The exact format for the map file is not required since they are created and edited from within **12d** Model by the option

File i/o => Map file

N Plotters and Plotting

The method of creating plots and sending them to a plotter or a Cad system such as AutoCad or Microstation, varies from site to site.

12d Model provides an array of set ups and options to enable the user to tailor the plotting system.

Since the plotting set ups and options are scattered throughout **12d** Model, the rationale behind the plotting set ups will be summarized in this chapter.

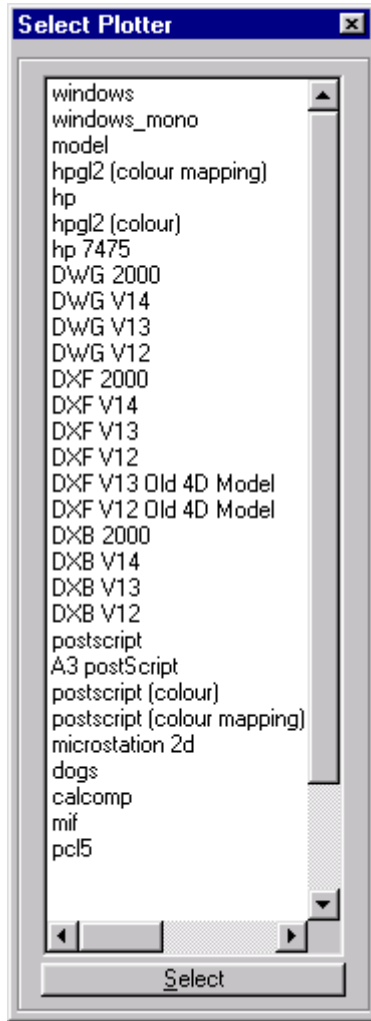

Supported Plotters

When creating a **plot**, **12d** Model can either use a Windows printer driver to plot directly, or instead of driving the plotter directly, create a computer disk file (the plot file) containing the relevant plotter instructions for producing the plot (which is then sent to the plotter), or in the case of the plotter type **model**, create a **12d** Model model.

The **plot file** can be written in a variety of formats. Currently, **12d** Model supports the formats:

windows	Windows colour printer, or grey scale on mono printers
windows_mono	Windows mono printer - uses black, not grey scale
hp	standard HPGL with all of one pen being plotted before the next pen is used
hp (no sort)	standard HPGL with no pen sorting
hp 7475	small HP plotter, common hp emulation mode for lasers
hpgl 2 7600	HPGL 2 for HP 7600 mono plotter
hpgl 2 (colour)	standard HPGL 2 for colour plotters
hpgl 2 (colour mapping)	standard HPGL 2 for colour plotters using a plotter mapping file
dxg	2d DXF file
dwg	2d DWG file
pcl5	pcl5 format
eagle single	Eagle single precision binary model (not in the base module)
eagle double	Eagle double precision binary model (not in the base module)
postscript	Postscript format (generally for laser printers)
postscript (colour)	colour postscript format (generally for laser printers)
postscript (colour mapping)	colour postscript format using a plotter mapping file
dgn 2d	Intergraph/Microstation binary model (.dgn file)
dogs	Dogs parametric format
calcomp	Calcomp plot format
mif	frame maker interface format.
model	creates a 12d Model model

By default, this list of plotters appears when RB is clicked in a **plotter panel field**

windows colour plotter
windows mono plotter
12d Model model
hpgl2 plotter using a mapping file
hp pen plotter
hp 7475 A3 plotter
AutoCAD dwg file

AutoCAD dxf file

postscript plotter
A3 postscript
postscript plotter using a mapping file
Intergraph/Microstation dgn file
DOGS file
Calcomp plotter
FrameMaker file
PCL5 printer

However, a user defined list of available plotters, with user definable names and properties, can be set up and used instead of the default list. User defined plotters will be documented later in the section "User Defined Plotters" .

Please continue to the next section "Sending Plots to a Plotter" .

Sending Plots to a Plotter

When plots are created, **12d** Model can fire up a user supplied script/program with the plot file as the first argument. By checking the plot name suffix, the script could for example, decide which plotter the plot must be sent to.

The environment variable

PLOTTER_4D *points_to_script/program*

points to the script/program which can be fired up whenever a plot is generated. The name of the plot is given as the first script parameter of the script.

If the tick box **Send plots** in the panel tab **System Settings** of the panel **Defaults** (given by the menu option **Utilities => Default**) is set to **on**, the plotter script is run as each plot is created.

If more than one plot is created by an option (e.g. x plot) then the script is called separately for each of the plots.

An example of a script to send the plot to port lpt1 for Windows NT would be

```
@echo off
copy %1 lpt1
```

An example for Windows NT which looks for hp files is

```
@echo off
echo.
echo -----
:next_file
if "%1" == "" goto done
echo %1 | find /I ".hp" > nul
if ERRORLEVEL 0 if not ERRORLEVEL 1 goto hp_plotter
echo Plotting file %1
shift
goto next_file
:hp_plotter
echo Plotting %1 to HP plotter
copy %1 \\server_name\printer_name
shift
goto next_file
:done
echo -----
```

Environment variables are fully defined in the section “Environment Variables” of the Appendix “Set Ups”

Please continue to the next section “Mapping Colours to Plotter Pens” .

Mapping Colours to Plotter Pens

12d Model uses up to 10,240 different colours and when it comes to plotting, it must be decided how these colours are mapped for the particular plotter being used.

For some plotters, colours may be used whereas for mono plotters, line thickness and linestyles may be needed.

When plotting to CAD systems such as AutoCad and Microstation, no physical plot is created but the plot image may need to be send to special colours, layers and styles in the Cad system.

For plotting to actual plotters, there are two methods of specifying the colour to pen mappings.

- (a) **pen mapping** - a simple colour to pen mapping, mainly used for pen plotters
- (b) **plotter mapping** - a colour to pen mapping plus the red, green, blue definition for colours used on the plotter. This is mainly for electrostatic, inkjet and bubblejet plotters.

Plotter mapping is an extension of pen mapping and only one of the two is used for a plot.

Pen Mapping

For all plotters types except Eagle, the Plots=>Pen mapping option can be used to define the correspondence between **12d** Model colours and plotter pens for the first sixteen colours.

The other colours are given in the **colours.4d** file. For Eagle plots, the **eagleplt.pmf** file is used to map colours to pens.

The pen mapping option is only used if a plotter mapping is **not** being used (see next section).

When starting a new project or entering an existing project, the default pen mapping table is defined by the **colours.4d** file.

Once inside the project, any pen number in the table can be modified by changing the appropriate pen field and then selecting the **set** button. The modified table is stored until **12d** Model is quit or the user changes to another project.

The pen mappings for colours above sixteen are given in the **colours.4d** file but can not be displayed or modified by the **colour to pens** panel.

Whenever a plot is created using non-eagle plotter types, the colours are mapped to the pen numbers given in the **colours to pen** table before writing out the plot file.

For Eagle plots, the **eagle_plotter.emf** file is used to map colours to pens.

Note - when **12d** Model is started up again or the user changes to a new project, the table reverts to its default settings as given in the **colours.4d** file.

Colours.4d

The **colours.4d** file defines the distinct colours for drawing in any **12d** Model view.

The **colours.4d** file is also used to define the **default plotter pen** associated with the colour.

See "Colours" in the Appendix "Set Ups"

Plotter Mapping

The **plotter mapping file** can be used use with pen plotters but is more specifically designed for electrostatic and inject plotters and allows the user to

- (a) map **12d** Model colours to particular plotter pens and also specify a width (or weight) to be used for PCL5, HPGL2, postscript and all Windows plotters.
- (b) specify the red, green and blue mix for pens on HPGL2, colour postscript and all Windows

plotters

The plotter mapping file to be used can be set using

- (a) the option Plots=>Plotter mapping
- (b) set by the environment variable PLOTTER_MAPPING_4D, or the file pmf.4d
- (c) defined for a particular plotter in the user defined plotters file.

There are also two special formats of the plotter mapping file which are used for plotting to Autocad dxf and Intergraph dgn. The special mapping files use the 12d Model colour as a key to tables which control how the information is passed to DXF and DGN.

- (d) .tbl file used with plotting to Intergraph dgn
- (e) .amf used with plotting to Autocad dxf

The plotter mapping file to be used can be set using

- (a) the option Plots=>Plotter mapping
- (b) set by the environment variable PLOTTER_MAPPING_4D, or the file pmf.4d
- (c) defined for a particular plotter in the user defined plotters file.

Plotter Mapping File

The plotter mapping file (.pmf) consists of two sections:

- (a) pen_mapping table to define the which pen a 12d Model colour is mapped to, and the weight for the pen.
- (b) pen_colour table which defines the red, green and blue values to be used for the pens on the plotter.

The format of the plotter mapping file (.pmf) is

```

pen_mapping {                                // pen mapping and weight table

//      12d      plotter      weight
//      colour   pen no      for pen

           0         1         0.15
           1         2         0.25
           3         1         0.5
//      etc.
}
pen_colours {                                // pen colours table

// plotter
// pen      red      green      blue      values 0-255
   0         0         0         0         // pen 0 is black
   1        255         0         0         // pen 1 is red
//      etc.
}

```

The **colour n** and **pen n** and the **default weight** for n=0,1...255 is used to initially fill up the 10,240 positions of the **pen_mapping** weight table.

The **pen n** and the **rgb** of the **default colour** (take its rgb from the colour_map.def file) for n=0,1...10,240 is used to fill up the 0,240 rgb positions of the **pen_colours** table before the plotter mapping file is used.

If the Plots =>Plotter mapping option is used, and the **merge colours.4d** flag is set, the rgb columns

from the colours.4d file are used to define the pen_colours (first row is pen 0, second row is pen 1 etc.), and the pen mapping number is used to construct the pen_mapping table.

The plotter mapping file is then processed and overwrites any of the above initial mapping values.

If the plotter type is **dgn** and the map file is a table file with the extension of .tbl, the plotter will use the colour being plotted as the key in the table file and so allows the mapping from the plot colour directly into dgn level, weight, style and colour. See the next section for an example of a table file.

If the plotter type is **dxg** and the map file is an AutoCAD mapping file with the extension of .amf, the plotter will use the colour being plotted as the key in the mapping file and so allows the mapping from plot colour directly into layer name, Autocad colour and linestyle. Note that if Autocad colour or linetype is BYLAYER, then 12d Model uses the correct values in Autocad. The * character means that the field is ignored. See the next section for an example of an Autocad mapping file.

User Defined Plotters

A file can be set up to define the plotters that appear in the **plotter type** panel field, and the properties of the plotters.

It is possible to customize:

- (a) the name of the plotter
- (b) the start and end sequence that is sent to the plotter
- (c) for each plotter, whether pen or plotter mapping occurs.

The full set of user defined plotters is given in a file called **plotters.4d** which is searched for in the standard set up paths, or is pointed to by the environment variable

PLOTTERS_4D filename

In the plotter file, the definition of a **plotter** of a given name *plotter_name* is set out as:

```
plotter plotter_name {  
    set_up_commands  
}
```

plotter_name must not be blank and if it includes imbedded spaces, it must be enclosed in double quotes “.

The plotter itself is defined inside the braces where there can be zero or more plotter set up commands from the list:

```
colours  
engine  
extension  
footer  
header  
map_file  
map_pens  
output_cmd
```

Description of the Plotter Set Up Commands

engine windows | dxf_4d | dxf_12 | dxf_13 | dxf_14 | dxf_2000 |
 dwg_4d | dwg_12 | dwg_13 | dwg_14 | dwg_2000
 dgn | dogs | hpgl | hpgl2 | hpgl_7475 |
 calcomp | model | mif | postscript

extension ".???"

extension added to the file name used for the plot file written out by this plotter.

map_file *plotter_mapping_file_name*

points to a plotter mapping file which is used to redirect colours for any plotter. For hpgl2 and postscript, it also defines the pen weights (widths).

If **map_file** is not set and a global mapping file is specified, then it will be used as the plotter mapping file. Otherwise the pen mapping table is used.

If the **engine** is **dgn** and the **map_file** is a table file with the extension of .tbl, the plotter will use the colour being plotted as the key in the table file. This allows the mapping from the plot colour directly into dgn level, weight, style and colour.

If the **engine** is **dxf** and the **map_file** is an Autocad mapping file with the extension of .amf, the plotter will use the colour being plotted as the key in the mapping file. This allows the mapping from plot colour directly into layer name, Autocad colour and linestyle. Note that if Autocad colour or linetype is BYLAYER, then 12d Model uses the correct values in Autocad. The * character means that the field is ignored.

map_pens true | false

if true, it uses the specified **map_file**, or if **map_file** is false, it doesn't use any mappings (**map_file**, global plotter mapping file or pen mapping table). It leaves the pen number untouched. This was used in the hpgl2 colour and postscript colour - the screen colours were preserved. This can now be done for any plotter.

This is ignored when the **map_file** is used as a tbl file (plotter engine is dgn and the **map_file** has an extension of .dgn - any mapping is occurring via the tbl file where colour is the key).

This is ignored when the **map_file** is used as a amf file (plotter engine is dxf and the **map_file** has an extension of .dxf - any mapping is occurring via the .dxf file where colour is the key).

output_cmd path to a *script* or *program*

for this plotter, the given script or program is used on the created plot file. This replaces the PLOTTER_4D definition of script or program for this plotter.

colour true | false

used in hpgl2 and postscript.

If false, then for postscript don't send the rgb for colours and for hpgl2, it doesn't send down the block of information with the number of pens and the rgb for each pen. That is, if false, it stops hpgl2 and postscript writing out the colour definition commands.

header and footer

The **header** information is placed in the plot file before any plot commands and the **footer** information is placed at the end of plot file after all the plot commands.

The format for the for the **header** of **footer** is:

```
header { // this information is placed in the plot file before any plot commands
  lines of text which can include plotter variables
}
```

```

or
  footer {      // this information is placed at the end of the plot file, after the plot commands
                lines of text which can include plotter variables
  }

```

Each line of text is surrounded by quotes. For example, "this is some stuff".

The *plotter_variables* used in the **header** or **footer** are:

```

  username
  filename
  date
  time
  sheet_width
  sheet_height
  page_number - not used
  minimum_x, minimum_y // plotter dependent
  maximum_x, maximum_y // plotter dependent

```

and are included in the text by preceding them by a + and also following them by a cross if more text follows. For example:

```
"the user is " + username+" of 4D Solutions"
```

The appropriate information is substituted for the *plotter_variables* when a plot is created.

Hence

```
"the user is " + username+" of 4D Solutions"
```

would give

```
"the user is fred of 4D Solutions"
```

A *plotter_variable* may not be appropriate for a particular plotter and if a *plotter_variable* is specified but not used for a plotter, it is substituted by *blank*.

If **header** or **footer** is not specified, then appropriate default information for the plotter is used.

The **header** and **footer** *set_up_commands* are not used by all plotters. If they are not used for a particular plotter, the **header** or **footer** command is ignored.

At present, only the plotters hpgl, hpgl2, postscript and dxf use **header** and **footer**.

minimum_x etc for postscript, it is the extent of the plot in mm
sheet_width, *sheet_height* for postscript in mm

For hpgl2

```
sheet_width, sheet_height          in mm/40.
```

Example of a Plotters.4d File

An example of a plotters.4d file is:

```
// -----  
// File:    plotters.4d  
// Date:    25 January 1997  
// Use:     User definable plotter names  
// -----  
  
plotter "Windows" {                // Windows printer drivers  
  engine windows  
  colour true  
  map_pens true  
  map_file "windows_colour.pmf"  
}  
plotter "Windows mono" {          // Windows printer drivers  
  engine windows  
  colour false  
  map_pens true  
  map_file "windows_mono.pmf"  
}  
plotter "HP Colour" {             // hp plotter using hpgl2  
  engine hpgl2  
  colour true  
  map_pens true  
  map_file "jetcolor.pmf"  
  output_cmd "print -s://melba/jet_design"  
  extension ".hp2"  
}  
  
plotter "HPGL Pen plotter" {      // hp pen plotter using hpgl  
  engine hpgl  
  map_file "jetcolor.pmf"  
  output_cmd "print -s://melba/devel_hp4v"  
  extension ".hp"  
}  
  
plotter "Model" {                 // plot to a 12d Model model  
  engine model  
  extension ""  
  map_pens false                   // don't map colours  
}  
  
plotter "DGN" {                   // output to a Microstation dgn file  
  engine dgn  
  extension ".dgn"  
}  
  
plotter "DGN with tbl" { // define a dgn plotter using an output table file  
  engine dgn  
  extension ".dgn"  
  map_pens true // ignored where the map_file is used as a tbl file  
  map_file "vicplot.tbl"  
}
```

```
plotter "DXF 2000" { // output to a dxf file
  engine dxf_2000
  extension ".dxf"
}
plotter "DXF 2000 with amf" { // output to a dxf file using an autocad map file
  engine dxf_2000
  extension ".dxf_2000"
  map_file "acadplot.amf"
}
```

Definition and Example of a .tbl File

An example of an output mapping file for use with an Microstation (Intergraph) dgn plotter:

```
// -----
// File: vicplot.tbl
// -----
// column 112d colour name      (any length - but only 1st four characters passed)
// column 2Vic roads code      (only 1st four characters passed)
// column 3AS2482 feature code
// column 4description (any length but if embedded spaces then must be quoted)
// column 5line level          (between 1 and 64)
// column 6line colour         (between 1 and 256)
// column 7line weight         (between 1 and ?)
// column 8line style
//
// notes: if column 2 is a * then the 12d name is transmitted (up to 4 characters that is)
//        columns 9 through 16 are only used for point strings which map into characters

1 PM  38010000 "Permanent Survey Mark  " 49 0 1 0
2 BM  38020000 "Bench Mark              " 49 0 1 0
3 TPEG 31000001 "Title peg              " 50 0 1 0
4 STN  38100000 "Instrument Station     " 50 0 1 0
5 SM   38000000 "Survey mark (general)  " 50 0 1 0
6 PCON 38040001 "Photo control point   " 50 0 1 0
7 CHEK 38000001 "Check profile/point   " 52 10 3 0
8 TRIG 38010000 "Trigonometric Station " 50 0 3 0
9 BMQS 38020001 "Bench Mark QS-1      " 49 11 1 0
10 BMS  38020002 "Bench Mark S-2      " 49 11 1 0
11 BMSH 38020003 "Bench Mark SH-1     " 49 11 1 0
12 RM   38000001 "Reference Mark - General " 50 11 1 0
* ROD  38000002 "Reference Mark - Rod   " 50 11 1 0 // everything else
```

Definition and Example of a .amf File

An example of an AutoCad output mapping file for use with an Autocad plotter:

```
// -----
// File: acadplot.amf
// -----
// column 1 match colour- can include wild chards * and wild characters ?
// column 2 new name - not output to DXF
// column 3 ACD layer -
// column 4 ACD colour- * for 12d Model colour (mapped to ACD),
//              BYLAYER for ACD BYLAYER
// column 5 ACD line type- * for 12d Model linestyle,
//              BYLAYER for ACD BYLAYER
// column 6 ACD text style- not yet used, * for 12d Model text style
//
// Notes:
// 1. column 5 (ACD colour) can only be a number between 0 and 256, or * or BYLAYER
// 2. The DXF file produced needs to be loaded into an existing Autocad drawing
//    which has the ACD layers and linestyles defined.
// column 1   2       3       4           5           6
//
1  CONT  ljpg1  1           1           *
2  TOP   ljpg2  2           CONTINUOUS *
3  TOP   *      3           *           *
4  TOP   ljpg4  *           BYLAYER     *
5  TOP   ljpg5  BYLAYER  DASH        *
```

Microstation (DGN) Plot Seed File

When creating dgn plot files in Microstation (Intergraph) DGN format, a Microstation (Intergraph) DGN seed file can be used.

The folder containing the seed files can be pointed to with the environment variable MS_SEEDFILES_4D:

```
MS_SEEDFILES_4D          folder
```

The Microstation seed file is set by the Plots=>DGN plot seed file option.

Sheet Sizes

For plot frames, long and x plots, the overall size of the plot sheet can be given by a pop-up containing defined sheet size.

The sheet size names, width and heights can be specified by the user in a file named **sheets.4d** which is in the normal set up areas, or is pointed to by the environment variable

```
SHEET_SIZES_4D          file          // file of plotter sheets sizes
```

The layout of the sheet sizes file is given in the section "Sheet Sizes" in the Appendix "Set Ups"

Environment variables are fully defined in the section "Environment Variables" of the Appendix "Set Ups"

Hardware Arcs

When plotting arcs, the arc can either be broken into a series of straight lines within 12d Model, or plotted using the arc command (if it exists) for the relevant plotter.

The initial default for hardware arcs is set by the environment variable HARDWARE_ARCS_4D:

```
HARDWARE_ARCS_4D      1          use hardware arcs          default
                      0          hardware arcs are not used
```

but this can be overridden by the option Plots=>Hardware arcs.

Environment variables are fully defined in the section "Environment Variables" of the Appendix "Set Ups"

Interface Colours

When drawing interface strings in 12d Model, cut areas are denoted in red, fill areas in green and sections on the surface in yellow.

However, when plotting it is convenient to be able to map the interface colours to other colours.

This panel is used to define new colours for the interface colours, and the new colours are then mapped to pens using the pen mapping table or plotter mapping file.

The colours used for plotting the interface colours is set from the option `plots=>interface colours`

Text Units

Text occurs in 12d Model plots in a number of ways -

- ▲ plotting **text strings** and **4d strings**
- ▲ automatic text such as grid values, x-section and long-section plot annotation.
- ▲ text within linestyles.

The most difficult thing about text is that because of the different uses of text, there needs to be more than one systems of **units** to define text heights.

The height of text for a given textstyle is defined to be the height of a capital A. However, in 12d Model, there are three methods of defining the units for measuring this height.

- ▲ world units - the units used for data
- ▲ screen units - pixels (the screen is 1000 pixels wide)
- ▲ plot paper units - millimetres.

World Units

World units are the units of user data. For most users, the base unit for user data is metres. However 12d Model is a dimensionless system and the base unit is totally dependent on the user.

The height of world text when displayed in a view depends upon on the text height and the scale of the view.

When plotted, the height that world text appears on a plot sheet is the same as for any data defined in world units - the height depends on the **scale** used for the plot.

Text heights that are only given in world units have **(w)** after them.

For some text, the choice of units is either world or pixels. The text parameters then have a **(u)** after them.

Screen Units - pixels

When screen units (pixels) are used, the text is a fixed height on the screen. If the user zooms in on text given in pixels, the text remains the same height.

To have a height on a plot, screen unit text needs a height defined in millimetres.

For some screen text, both a pixel and a millimetre height is supplied when the text is defined.

For text with only a pixel height, there is a plotting multiplication parameter called **pixels-to-millimetres** which is used to convert pixel heights to plot paper heights. The value of pixels-to-millimetres is set using the `plots=>pixels to mm` option and is stored for the project.

Text heights that are only given in pixels have a **(pix)** or **(p)** after them.

For some text, the choice of units is either world or pixels. These text parameters then have a **(u)**

after them.

Plot Paper Units - millimetres

Text defined in plot paper units (millimetres) has a well defined height on a plot sheet.

Text heights that are only given in millimetres have **(mm)** after them.

Pixels to mm

To allow text and linestyles with only a pixel size to be plotted, a factor to convert pixels to millimetres is used.

When plotting, any text and linestyle defined **only** in pixel units is **multiplied** by the pixels-to-millimetre factor to determine its size in the plot.

For a new project, the initial value is loaded from the **defaults** file and is defined in this file by

```
PIXELS TO MM PLOT FACTOR      value
```

See “Defaults” in the Appendix “Set Ups”

The pixels-to-mm factor can be modified by the Plots=>Pixel to mm option.

The pixel-to-millimetres value is stored for the project

Environment variables are fully defined in the section “Environment Variables” of the Appendix “Set Ups” .

O Plot Parameters

Plot Frame Plot Parameter File

The plot frame section plot parameters are placed in a file with ending **.ppf**

Each parameter consists of a parameter name followed by one or more spaces and then the parameter value. There is only one parameter per line.

Anything on a line after a double forward slash // is considered to be a comment.

The set of all parameters for the plot frame plot is enclosed within a set of curly brackets { } with the header

```
plot_frame_plot "plot set name"
```

before the curly brackets.

That is,

```
plot_frame_plot "plot set name" {
    plot parameters
    one per line
}
```

If there is more than one `plot_frame_plot` parameter set in the file, only the first set is used.

There may also be parameter sets for other plot types such as `section_long_plot` in the same file. The other sets will be ignored when doing plot frame plots.

The only parameters not connected with title block file are

<code>view_name</code>	<code>view_name</code>	// name of view used for information // on the plot
<code>single_frames</code>	<code>frame_name</code>	// name of plot frame to be plotted
<code>model_of_frames</code>	<code>model_name</code>	// model of plot frames which may be // plotted as a group

Both these parameters exist in the **plot frames plot** panel and when the parameter file is first read, if either of these parameters exist in the plot parameter file then they will be used to replace the corresponding parameters in the panel.

However, if the parameters are subsequently modified in the panel, the new panel value will be the value used for plotting.

Title Block Information

A plot frame plot can have a standard 12d Model title block or a user defined title block.

For a user defined title block, the title block drawing commands are kept in a file whose name is given by the user when setting up the plot frame. The title block drawing commands are almost identical to the linestyle drawing commands.

If a user defined title block has been set for the plot frame, plot frame parameters can be used to pass information though to the title block.

User Title Block

Some of the plot parameters are used to pass information down to variables in a user defined title block specified in the plot frame.

The parameters are:

<code>time_format</code>	<i>text</i>	// format for \$time
<code>title_1</code>	<i>text</i>	// passed down to \$title_1
<code>title_2</code>	<i>text</i>	// passed down to \$title_2
<code>user_text_n</code>	<i>text</i>	// where n = 1,2,... 1000 // passed down to \$user_text_n
<code>start_page_number</code>	<i>integer</i>	// used as the starting value for \$page_number. // if missing, \$page_number starts at 1.
<code>start_drawing_number</code>	<i>integer</i>	// added to \$drawing_number in title block file // if missing, \$drawing_number starts at 1.
<code>drawing_number_prefix</code>	<i>text</i>	// passed down to \$drawing_number_prefix
<code>drawing_number_postfix</code>	<i>text</i>	// passed down to \$drawing_number_postfix

Notes

1. A warning is given if the keyword in a plot parameter file does not exist.
2. A warning is also given if the key word pair is defined more than once in a ppf.

Cross Section Plot Parameter File

The cross section plot parameters are placed in a file with ending **.ppf**

Each parameter consists of a parameter name followed by one or more spaces and then the parameter value. There is only one parameter per line.

Anything on a line after a double forward slash // is considered to be a comment.

The set of all parameters for the cross section plot is enclosed within a set of curly brackets { } with the header

```
section_x_plot "plot set name"
```

before the curly brackets.

That is,

```
section_x_plot "plot set name" {
    plot parameters
    one per line
}
```

If there is more than one section_x_plot parameter set in the file, only the first set is used.

There may also be parameter sets for other plot types such as section_long_plot in the same file. The other sets will be ignored when doing cross section plots.

The plot parameters are documented in following groups:

For the *Plot Sheet layout*, please continue to the section "Plot Sheet Layout".

Boxes and datum area, please continue to the section "Boxes and Datum Area".

Only for the Centre line case:

Datum area, please continue to the section "Datum Line".

Labelling the centreline, style etc., please continue to the section "Labelling the Centreline Chainage".

Only for the Boxes case:

Datum area, please continue to the section "Datum Line".

Labelling the centreline chainages, please continue to the section "Labelling the Centreline Chainage".

Defining boxes and what is labelled in them, please continue to the section "Defining Boxes".

For Both the Centre Line and Boxes case:

Graph area parameters, please continue to the section "Graph Area".

Grade labelling, please continue to the section "Grade Labelling".

Labelling points on x-sections, please continue to the section "Labelling Points of the X-Sections".

Labelling cuts, please continue to the section "Labelling Cuts of X-Sections Through Strings in a Model".

Hatching cut/fill, please continue to the section "Hatching Cut and Fill Areas".

Drawing extra x-sections, please continue to the section "Extra Models of X-Sections".

Sorting x-sections, please continue to the section "Sorting X-Sections by Chainage".

Title block information, please continue to the section "Title Block Information".

Panel modifying parameters, please continue to the section "Parameters that Modify Fields In the Cross Plot Panel".

Example, please continue to the section "Example of a Cross Section Plot Parameter File".

Plot Sheet Layout

X-sections are normally generated at chainages along a given centreline. This centreline chainage is stored with each x-section string.

The chainages of the actual x-sections are referred to as **offsets** from the centreline position rather than x-section chainages. The offsets of the x-section are set up so that the zero offset occurs where the x-section crossed the centreline string.

The x-sections along the centreline are stored in the one model (the primary model) which is then used to generate the cross section plot.

```
model_to_plot          text          // name of the model of x-sections
```

Each x-section from the primary model of x-sections generates its own sub-plot for which the x-section is the primary string. Hence the cross section plot consists of many individual plots drawn on one or more plot sheets.

Each plot sheet is considered to have only positive co-ordinates with the origin (0,0) in the left hand corner. The units for the plot are millimetres.

The overall size of the plot sheet is given by either a defined sheet size, or by the width and height of the plot given in millimetres and separated by one or more spaces.

```
sheet_size            text          // sheet name, or
                    "mm mm"       // sheet size: width height
```

The sheet size name, width and heights can be specified by the user in a file named **sheets.4d** which is in the normal set up areas, or is pointed to by the environment variable

```
SHEET_SIZES_4D       file          // file of plotter sheets sizes
```

The plotting area is restricted to within the plot sheet by giving margins which are:

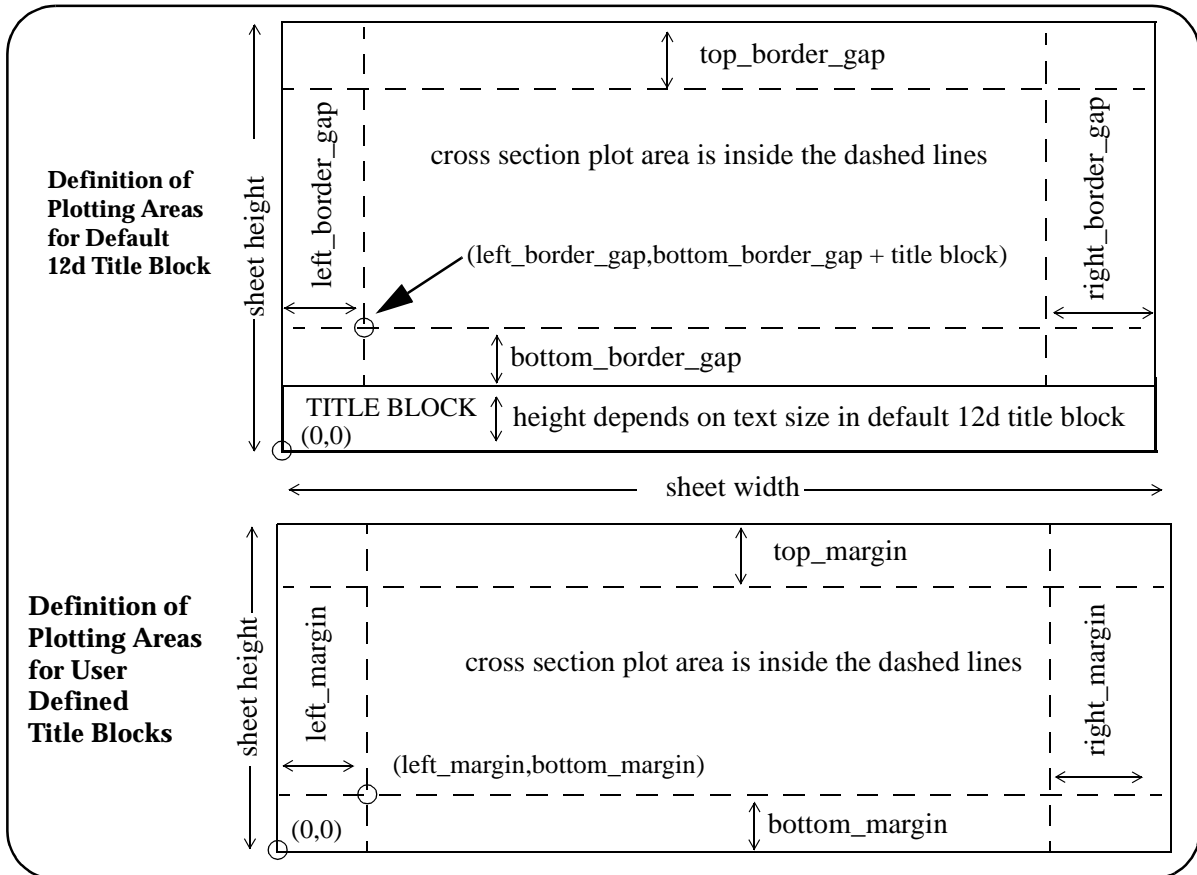

If a *User Defined Title Block* is used:

```
left_margin          mm
right_margin         mm
top_margin           mm
bottom_margin        mm
```

If the *default 12d title block* is used, then the size of the bottom of title block depends on the text size. The following parameters are used in the default title block case and the *bottom_border_gap* is added to the calculated height of the bottom of the title block.

```
left_border_gap      mm
right_border_gap     mm
top_border_gap       mm
bottom_border_gap    mm
```

Because the user can easily select from the plotting panel whether a User Defined Title Block or the default 12d title block is used, both sets of margin and gap parameters can exist in the one plot parameter file.

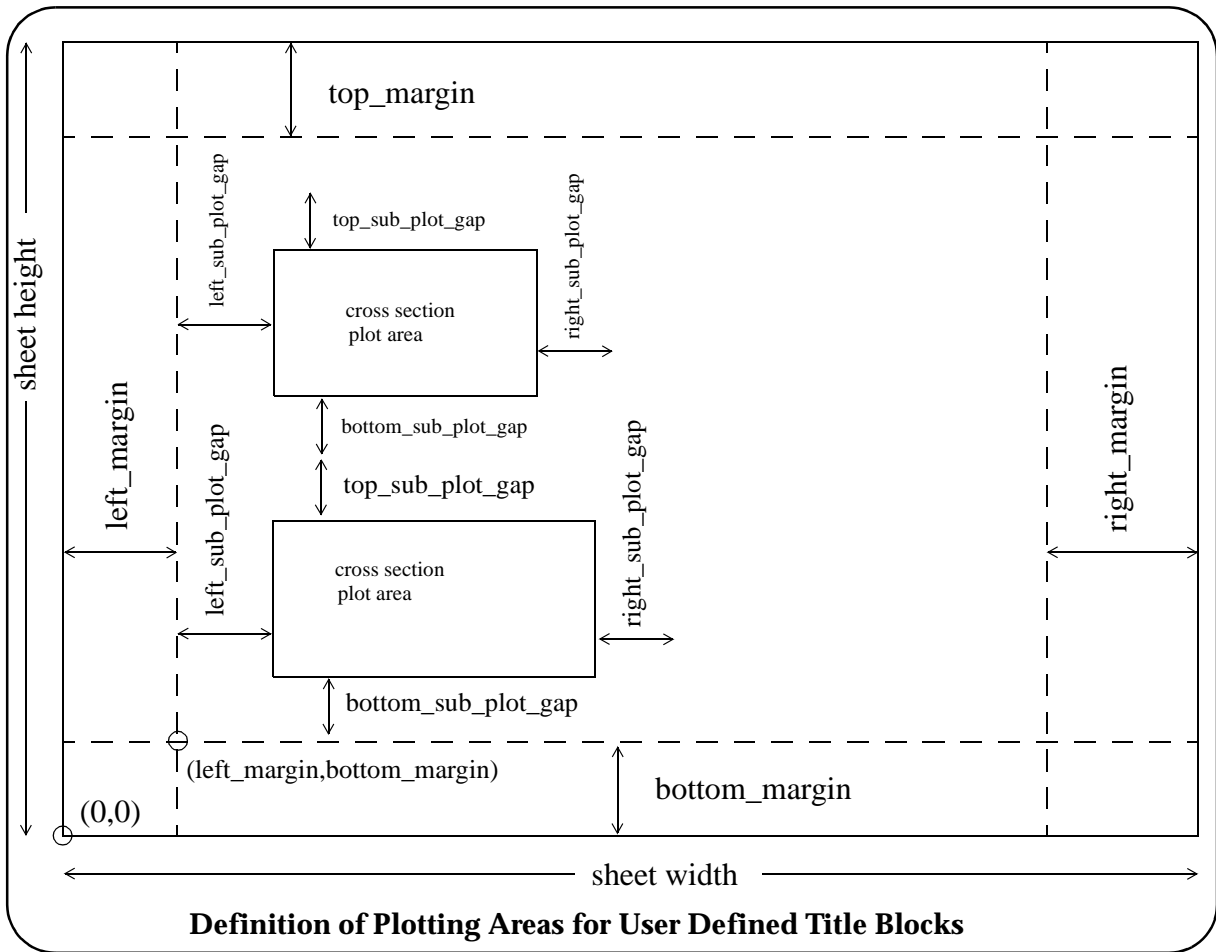

The x-sections are plotted in the order they occur in the x-section model and start being plotted at the bottom left hand corner of the cross section plotting area.

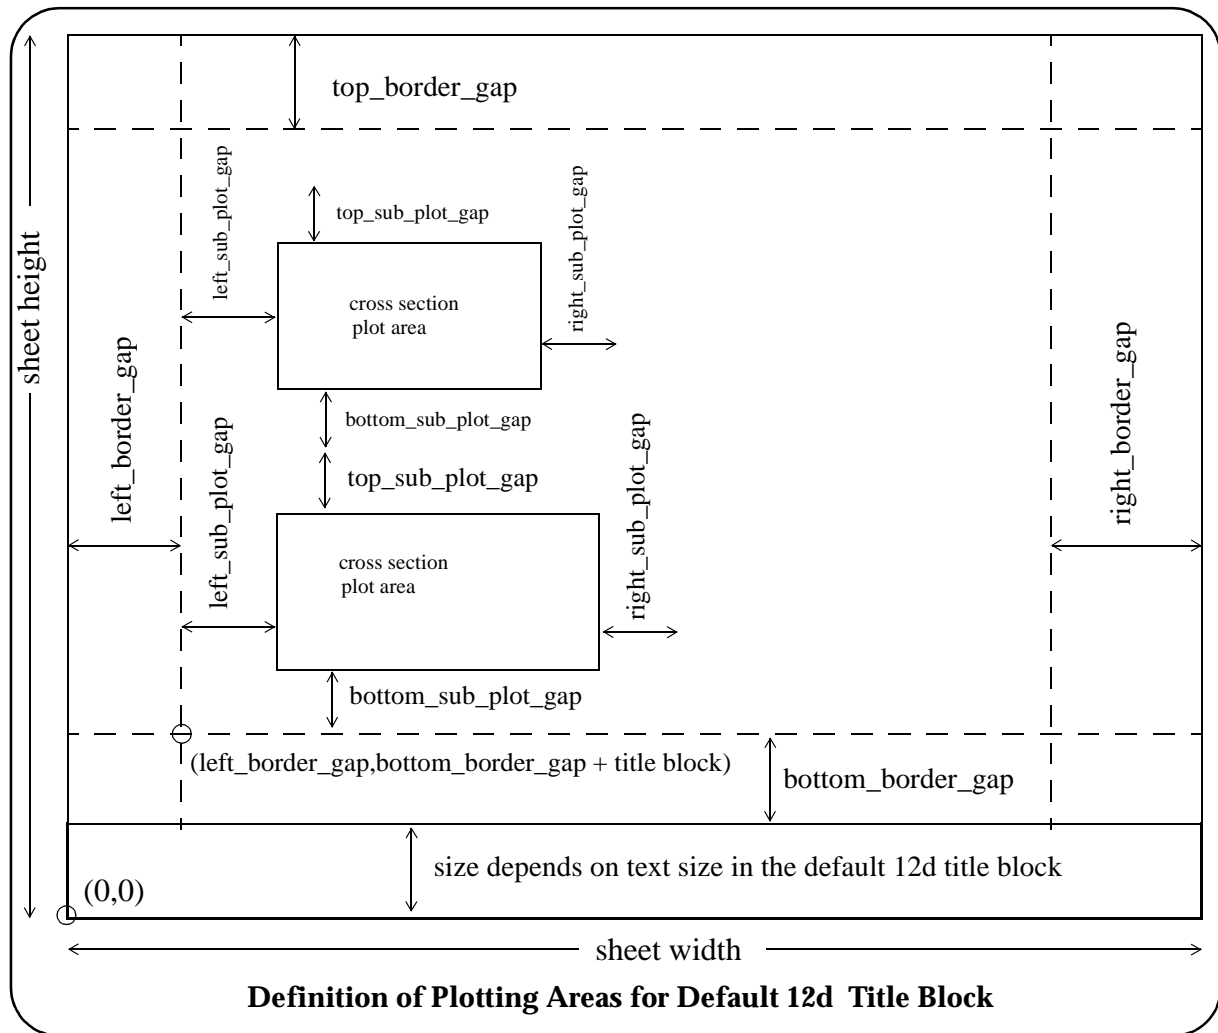

The individual x-section plots are then drawn going up the column, and when the column is full, start from the bottom of the next column.

When a sheet is full, a follow on sheet is created.

Each individual x-section sub-plot is positioned with the surrounding gaps:

left_sub_plot_gap	mm
right_sub_plot_gap	mm
top_sub_plot_gap	mm
bottom_sub_plot_gap	mm

If required, all the sub-plots in a column can be automatically positioned up so that the zero offsets (the centrelines) of each x-section line up.

```
line_up_cl          yes/no          // yes - line up zero offsets
```

The width of the plot can be a fixed distance left or right of the centre line (zero offset) or for the full section plus an extra left and right distance:

```
absolute_extensions  yes           // The section goes from the
                        // left_extension offset on the left to the
                        // right_extension offset on the right.
                        no           // The section goes for the entire section
                        // length plus the left and right extension
                        // distances.
left_extension        world-units   // left extension value
right_extension       world-units   // right extension value
```

The x-section can be drawn and labelled with either

- (a) centreline case - the x-section is plotted and an upright, and the offset and height value at the zero offset (normally the centre line position)
- (b) boxes case - the x-section is plotted and the heights of the x-section and the tins at all the x-section points are labelled in boxes under the plot of the x-section.

The x-section sub-plot itself consists of the three regions - graph, datum and boxes.

The **graph area** is the area where the actual plots of the strings are drawn. This exists for both the centreline and boxes case.

The **datum area** is the region between graph area and the datum line. This exists for both the centreline and boxes cases.

The **boxes area** is where the offset values and the heights for the strings drawn on the x-section plot are labelled. This only exists for the boxes case.

For both cases, the x-section sub-plot can be labelled with other information such as

- (a) grades across the x-section
- (b) points across the x-section
- (c) cuts the x-section makes through strings
- (d) cut and fill areas

All the required parameters will be described in the following sections.

Please continue to the next section “Boxes and Datum Area” .

Boxes and Datum Area

The x-section can be labelled with either

- (a) an upright, and the offset and height value at the zero offset (normally the centre line position)
- (b) the heights of the x-section and the tins at all the x-section points.

The choice is given by the parameter **label_type**:

```
label_type          "centre line"          // type (a)
                   boxes                   // type (b)
```

A datum line exists for both cases.

For the boxes case, a box area for the offset and heights is created below the datum line. The available parameters for tailoring the box area will be given after describing the datum line parameters.

For the centre line case, the centre line and offset and height of the centre line are shown.

In both cases, the actual cross section plot is drawn above the datum line in the graph area.

Please continue to the next section "Centre Line Case" for the centre line parameters.

Please continue to the section "Boxes Case" for the boxes parameters.

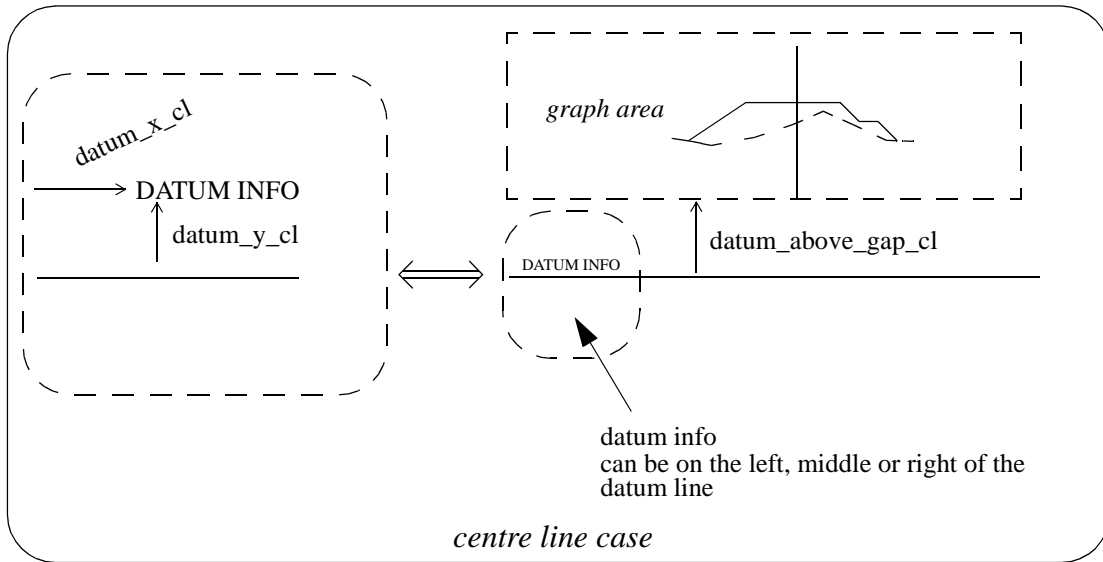

Centre Line Case

Datum Line

Each x-section sub-plot can be labelled with the datum value for the plot of the x-section string.

This DATUM INFO label is made up of the text strings:

"datum_name" followed by the *datum-value*
and is above the datum line.

For the centreline case, the graph area is positioned the distance **datum_above_gap_cl** above the datum line.

```
datum_above_gap_cl      mm           // dist from datum line to bottom of the
                               // graph area
```

The **datum_above_gap_cl** can be zero or positive.

The roundoff for the datum value is specified by the user (default 1.0) and the datum is automatically calculated for each sub-plot, and labelled.

The datum value can be placed on the left, centre or right side of the datum line.

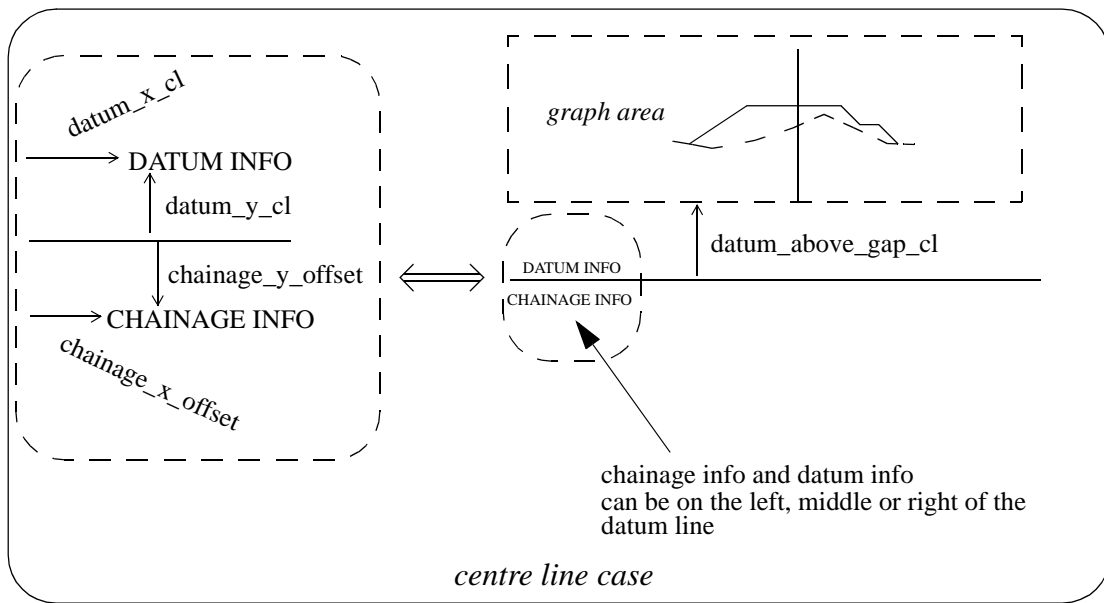

```
datum_roundoff          1.0          // value to roundoff the datum value to
                               // e.g. 0.5, 0.2, 1.0 (default 1.0)
datum_decimals           integer     // number of decimal places to display
                               // the datum value (default 1).
                               // If > 0, trailing zeros are removed after
                               // the decimal point.
                               // If < 0, the absolute value is taken as the
                               // number of decimal places to report
                               // i.e. no trailing zeros are removed
datum_side_cl            0           // datum text in middle of datum line
                               1       // " " " left of datum line (default)
                               2       // " " " right of datum line
datum_linestyle          linestyle   // datum line linestyle (default solid)
datum_name               text        // text to write before the datum value
datum_textstyle          text        // textstyle for datum information
datum_text_size          mm          // size of datum text and value
datum_colour             colour      // colour of the datum text
datum_line_colour        colour      // colour of the datum line
datum_text_justification_cl just     // justification for datum text
                               // NOTE - this is not normally required since
                               // by default the text justification is set to
                               // match datum_side_cl
datum_x_cl               mm          // distance to move the datum text
                               // along the datum line
datum_y_cl               mm          // distance to raise the datum text
                               // above the datum line (used to be
                               // called datum_offset)
```

The **datum_x_cl** and **datum_y_cl** can be positive, zero or negative.

Labelling the Centreline Chainage

Each x-section sub-plot can be labelled with the centreline chainage of the x-section string. This CHAINAGE INFO label is made up of the text strings:

"chainage_title" followed by the *chainage-value* and is drawn under the datum line.

The chainage value can be placed on the left, centre or right side of the datum line.

chainage_side_cl	0	// text in middle of datum line (default)
	1	// " " " " left of datum line
	2	// " " " " right of datum line

The parameters controlling the labelling are:

chainage_label	0/1	// 1 = label sub-plot with centreline // chainage, 0 don't label.
chainage_title	<i>text</i>	// text before the chainage value
chainage_decimals	<i>integer</i>	// number of decimals in the chainage // value. If <0, the absolute value // is taken as the number of decimal // places i.e. no trailing zeros are // removed for the values in the // chainage values.

chainage_colour	<i>colour</i>	// colour of the text
chainage_size	<i>mm</i>	// size of the text
chainage_textstyle	<i>colour</i>	// textstyle for the chainage label
chainage_text_justification_cl	<i>just</i>	// justification of the chainage text
chainage_x_offset	<i>mm</i>	// x position of text
chainage_y_offset	<i>mm</i>	// y position of text

The *chainage_x_offset* is measured from the beginning of the datum line.

The *chainage_y_offset* is measured from the bottom of the datum line with positive being **down**.

Centre Line Linestyle

The upright at the centre line position can have its own linestyle.

`cl_linestyle` *linestyle* //linestyle for centreline

Labelling the Design Height, X and Y Co-ordinates and Tin Heights at Offset Zero

The values of the height and X and Y co-ordinates of the **primary string** (usually the design cross section) at the zero offset can be labelled. Note that zero offset is normally where the alignment string cuts the cross section.

The heights of any tins (such as the natural surface) at the zero offset can also be labelled.

The labels are made up of:

pre_text value post_text

where *value* is either a height or a co-ordinate.

The label is positioned at either the left, right or middle of the datum line, with an x and y adjustment and a rotation.

Parameters for labelling the X Co-ordinate at Zero Offset:

primary_x0_draw_mode	0	// don't draw the label -default
	1	// draw the label
primary_x0_position	0	// label in middle of datum line (default)
	1	// " " " " left of datum line
	2	// " " " " right of datum line
primary_x0_pre_text	text	// pre-text for label - def " "
primary_x0_post_text	text	// post-text for label - def " "
primary_x0_decimals	integer	// number of decimal places to display - def 1
		// If > 0, trailing zeros are removed after
		// the decimal point
		// If < 0, the absolute value is taken as the
		// number of decimal places to report
		// i.e. no trailing zeros are removed
primary_x0_x	mm	// x adjustment to position of label - def 0
primary_x0_y	mm	// y adjustment to position of label - def 0
primary_x0_angle	degrees	// angle of the label - def 0
primary_x0_colour	colour	// colour of the label
primary_x0_size	mm	// size (in mm) of the label
primary_x0_textstyle	textstyle	// textstyle of the label
primary_x0_justify	just	// justification for text

Parameters for Labelling the Y Co-ordinate at Zero Offset:

primary_y0_draw_mode	0	// don't draw the label -default
	1	// draw the label
primary_y0_position	0	// label in middle of datum line (default)
	1	// " " " " left of datum line

	2	// " " " right of datum line
primary_y0_pre_text	text	// pre-text for label - def " "
primary_y0_post_text	text	// post-text for label - def " "
primary_y0_decimals	integer	// number of decimal places to display - def 1
		// If > 0, trailing zeros are removed after
		// the decimal point
		// If < 0, the absolute value is taken as the
		// number of decimal places to report
		// i.e. no trailing zeros are removed
primary_y0_x	mm	// x adjustment to position of label - def 0
primary_y0_y	mm	// y adjustment to position of label - def 0
primary_y0_angle	degrees	// angle of the label - def 0
primary_y0_colour	colour	// colour of the label
primary_y0_size	mm	// size (in mm) of the label
primary_y0_textstyle	textstyle	// textstyle of the label
primary_y0_justify	just	// justification for text

Parameters for Labelling the Height of Primary String at Zero Offset:

primary_height_draw_mode	0	// don't draw the label -default
	1	// draw the label
primary_height_position	0	// label in middle of datum line (default)
	1	// " " " left of datum line
	2	// " " " right of datum line
primary_height_pre_text	text	// pre-text for label - def " "
primary_height_post_text	text	// post-text for label - def " "
primary_height_decimals	integer	// number of decimal places to display - def 1
		// If > 0, trailing zeros are removed after
		// the decimal point
		// If < 0, the absolute value is taken as the
		// number of decimal places to report
		// i.e. no trailing zeros are removed
primary_height_x	mm	// x adjustment to position of label - def 0
primary_height_y	mm	// y adjustment to position of label - def 0
primary_height_angle	degrees	// angle of the label - def 0
primary_height_colour	colour	// colour of the label
primary_height_size	mm	// size (in mm) of the label
primary_height_textstyle	textstyle	// textstyle of the label
primary_height_justify	just	// justification for text

Parameters for Placing Some Text:

extra_text_draw_mode	0	// don't draw the label -default
	1	// draw the label
extra_text_position	0	// label in middle of datum line (default)
	1	// " " " left of datum line
	2	// " " " right of datum line
extra_text	text	// text for label - def " "
extra_text_x	mm	// x adjustment to position of label - def 0
extra_text_y	mm	// y adjustment to position of label - def 0
extra_text_angle	degrees	// angle of the label - def 0
extra_text_colour	colour	// colour of the label
extra_text_size	mm	// size (in mm) of the label
extra_text_textstyle	textstyle	// textstyle of the label
extra_text_justify	just	// justification for text

Parameters for Labelling the Height of a Tin at Zero Offset:

A section along the primary string through each tin on the section view is automatically drawn

on the cross section plot but the user can specify whether the tin height at the zero offset is labelled or not.

Hence although there may be a number of tins drawn on the section plot, not all of them need to have their height at zero offset labelled.

The default order for labelling the tins is the order that they were added to the view but it is possible to specify which tin is used for labelling by giving the tin name rather than just using the tin on the section view.

In fact, it is possible to use **any tin** in the project to **label** the height at zero offset, **not just those drawn** on the section view.

```
tin_n_name          text          // n=1, ... no of tins on the section view.
                               // use the tin called text to label the nth
                               // row of tin heights.
```

If a tin of the name given by ***tin_n_name*** does not exist, then the plot is not produced and an error message is given.

The parameters for labelling the height of the tin at zero offset are:

```
tin_n_height_draw_mode    0          // don't draw the label -default
                          1          // draw the label
tin_n_height_position     0          // label in middle of datum line (default)
                          1          // " " " " left of datum line
                          2          // " " " " right of datum line
tin_n_height_pre_text     text       // pre-text for label - def " "
tin_n_height_post_text    text       // post-text for label - def " "
tin_n_height_decimals     integer    // number of decimal places to display - def 1
                               // If > 0, trailing zeros are removed after
                               // the decimal point
                               // If < 0, the absolute value is taken as the
                               // number of decimal places to report
                               // i.e. no trailing zeros are removed
tin_n_height_x            mm         // x adjustment to position of label - def 0
tin_n_height_y            mm         // y adjustment to position of label - def 0
tin_n_height_angle        degrees   // angle of the label - def 0
tin_n_height_colour       colour    // colour of the label
tin_n_height_size         mm        // size (in mm) of the label
tin_n_height_textstyle    textstyle  // textstyle of the label
```

Labelling the Centre Line Offset and Height

In the centre line case, the value of the height of the **primary string** (usually the design cross section) at the zero offset can be labelled. This is normally where the alignment string cuts the cross section.

The label is made up of the texts:

primary_title offset_title offset_value height_text height_value

NOTE: These parameters have now been superseded. The parameters for labelling the height of the primary string at zero offset covers this case. To use the zero offset parameters instead, the *primary_height_pre_text* would include all text required for the Primary_title, offset_title, offset_value and height_text (offset_value is always 0.0).

The parameter *primary_mode_cl* controls whether the **primary_title** is included in the label.

primary_mode_cl	0	// don't include primary_title, primary_value
	1	// incl. primary_title, primary_value default

The parameter *height_mode_cl* controls whether the **height_title** and **height_value** are included in the label.

height_mode_cl	0	// don't include height_title, height_value
	1	// include height_title, height_value default

The parameter *offset_mode_cl* controls whether the **offset_title** and **offset_value** are included in the label.

offset_mode_cl	0	// don't include offset_title, offset_value
	1	// include offset_title, offset_value default

The label can be placed on the left, centre of right side of the datum line.

offset_height_side_cl	0	// text in middle of datum line (default)
	1	// " " " " left of datum line
	2	// " " " " right of datum line

The size, colour, text justification and text style for the label is given by:

primary_title	text	//primary title
offset_title	text	// offset label (default "Offset")
height_text	text	// height text label (default "Height")
primary_textstyle	textstyle	// textstyle used for offset and height label
primary_colour	colour	//colour for offset and height label
primary_size	mm	//size of the offset and height label
offset_height_text_justification_cl	justif	// text justification
		// NOTE - this is not normally required since
		// by default the text justification is set to
		// match offset_height_side_cl

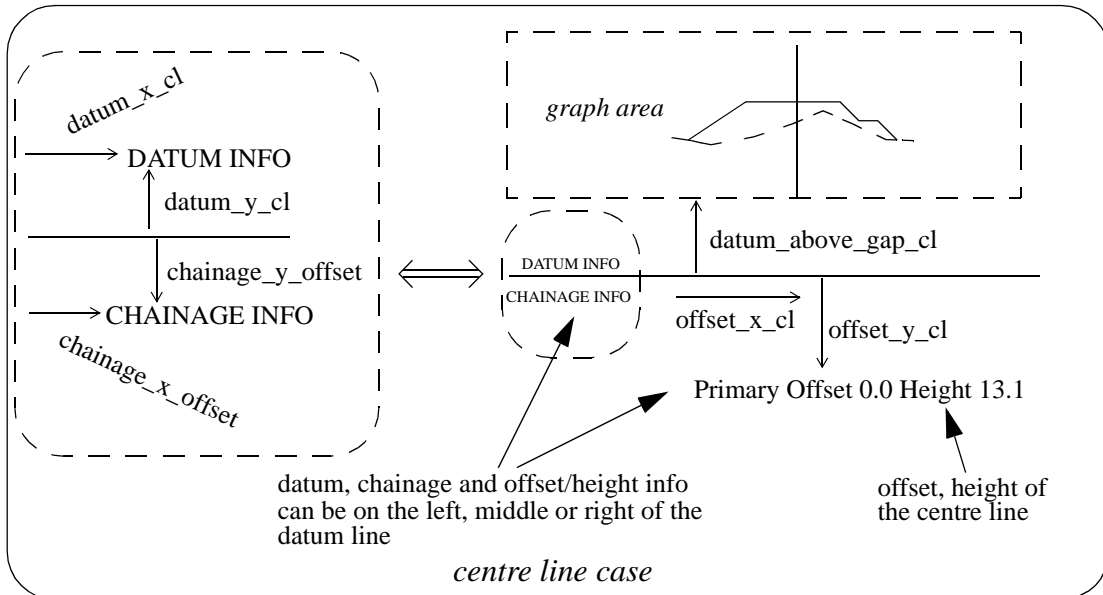

The number of decimals in the offset-value and height-value is controlled by:

number_of_decimals	integer	// number of decimal places in the offset,
		// height boxes. If <0, the absolute value
		// is taken as the number of decimal
		// places i.e. no trailing zeros are
		// removed for the values in the offset,
		// heights area.

The label is placed an distance *offset_x_cl* along the datum line and a distance *offset_y_cl* below the datum line of the plot.

offset_x_cl	mm	// distance to move the text along the
		// datum line
offset_y_cl	mm	// distance to shift the text below the
		// datum line

The *offset_y_cl* is measured from the datum line with positive being **down**.

Please continue to the next section “Boxes Case” for the boxes parameters.

Please continue to the section “Graph Area” if you are not using boxes parameters.

Boxes Case

Datum Line

For the boxes case, the **datum line** is positioned the distance ***datum_below_gap*** above the top of the boxes area and the graph area is then positioned the distance ***datum_above_gap*** above the datum line.

Hence the graph area is distance (*datum_below_gap* + *datum_above_gap*) above the top of the boxes area.

```
datum_above_gap      mm           // dist from datum line to bottom of the
                        // graph area
datum_below_gap      mm           // dist from datum line to the top of the
                        // boxes
datum_linestyle      linestyle    //linestyle for the datum line
```

The *datum_below_gap* and *datum_above_gap* can be zero or positive.

The roundoff for the datum value is specified by the user (default 1.0) and the datum is automatically calculated for each sub-plot, and labelled.

```
datum_roundoff      1.0           // value to roundoff the datum value to
                        // e.g. 0.5, 0.2, 1.0 (default 1.0)
datum_decimals      integer       // number of decimal places to display
                        // the datum value (default 1).
                        // If > 0, trailing zeros are removed after
                        // the decimal point.
                        // If <0, the absolute value is taken as the
                        // number of decimal places to report
                        // i.e. no trailing zeros are removed
datum_name          text          // text to write before the datum value
datum_textstyle     text          // textstyle for datum information
datum_text_size     mm           // size of datum text and value
datum_colour        colour       // colour of the datum text
datum_line_colour   colour       // colour of the datum line
datum_x            mm           // distance to move the datum text
                        // along the datum line
datum_y            mm           // distance to raise the datum text
                        // above the datum line (used to be
                        // called datum_offset)
```

The *datum_x* and *datum_y* can be positive, zero or negative.

Labelling the Centreline Chainage

Each x-section sub-plot can be labelled with the centreline chainage of the x-section string.

This CHAINAGE INFO label is made up of the text strings:

"chainage_title" followed by the *chainage-value*
and is drawn under the boxes area.

The parameters controlling the labelling are:

```
chainage_label      0/1           // 1 = label sub-plot with centreline
                        // chainage, 0 don't label.
chainage_title      text          // text before the chainage value
chainage_decimals   integer       // number of decimals in the chainage
                        // value. If <0, the absolute value
                        // is taken as the number of decimal
                        // places i.e. no trailing zeros are
                        // removed for the values in the
```

```

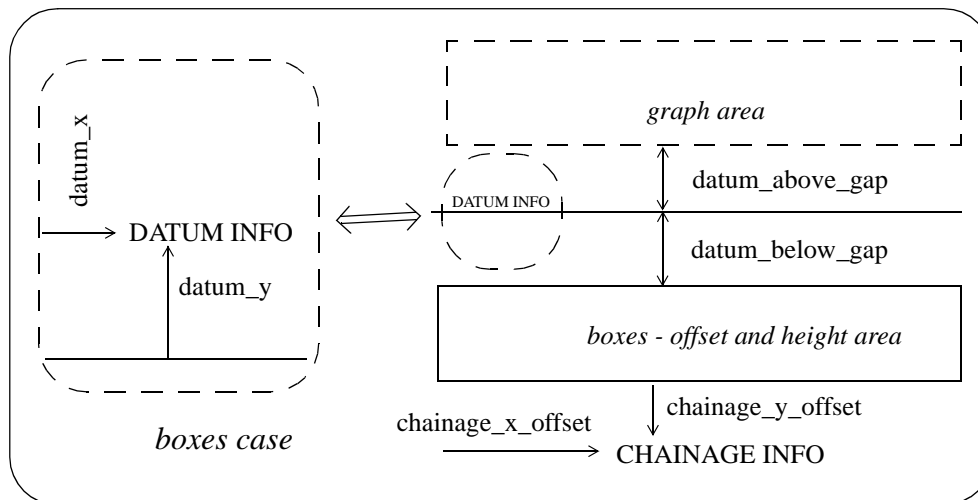

chainage_size           mm           // chainage values.
chainage_textstyle      colour      // size of the text
chainage_text_justification just    // textstyle for the chainage label
chainage_colour         colour      // justification of the chainage text
chainage_x_offset       mm           // colour of the text
chainage_y_offset       mm           // x position of text
                                // y position of text

```

The *chainage_x_offset* is measured from the beginning of the height boxes.

If *chainage_x_offset* is omitted, the text is centred on heights area.

The *chainage_y_offset* is measured from the bottom of the box area with positive being **down**.

Defining Boxes

When **boxes** is selected for *label_type*, the primary string (usually the design cross section) and each tin in the x-section sub-plot can be labelled with one or two lines of title, and the height at the offset position for each point in the primary string.

The **title** for the strings, is drawn in the **title area** of the **boxes area**.

The offsets/heights are drawn in the **heights area** of the **boxes area**.

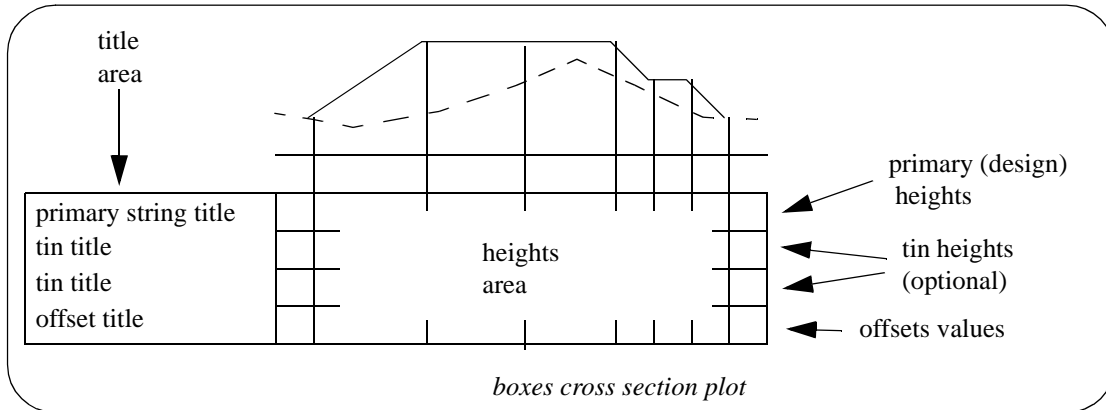

Consequently the boxes area is made up of rows of text consisting of:

string/tin titles followed by the **offset/height values** across the string/tin.

Each row is surrounded by lines to form a box.

The default order of the boxes from the bottom up is

- (a) offset title and values
- (b) tin title and heights - natural surface etc. (optional)
- (c) primary string title and heights - design x-section (optional)

The **title area** starts at the relative position (`left_sub_plot_gap`,`bottom_sub_plot_gap`).

The size of the title text is given by the **`title_box_text_size`** parameter.

The width of the title area is either given by the **`space_for_titles`** parameter, or if omitted, the required width is automatically calculated.

```
title_box_text_size      mm           // size of the titles in the boxes
space_for_titles        mm           // calculated if omitted
```

There can be two lines of title text and the title text, textstyle and colour can be set independently for the primary string and each tin.

The x position of the title text is the same for all the lines of title text and can be set to be a fixed distance from the left hand side of the boxes.

```
box_titles_x            mm           // distance to move the title text from the
// left hand side of the boxes
```

The **heights area** starts at the end of the title area.

The height text is written at right angles to the bottom of the boxes. It can be either top or bottom justified with respect to the box (**`box_text_justification`**).

The number of decimal places and the size of the heights text can also be specified.

The height of each individual box area is either given by the **`horizontal_line_spacing`** parameter, or if omitted, the required height is automatically calculated.

```
number_of_decimals     integer      // number of decimal places in the
// height boxes. If <0, the absolute value
// is taken as the number of decimal
// places i.e. no trailing zeros are
// removed for the values in the heights
// area.

text_size               mm           // size of the height values
offset_textstyle        textstyle    // textstyle for height text
offset_colour           colour       // colour of height text

box_text_justification  0           // bottom of individual boxes
                       1           // top of individual boxes

horizontal_line_spacing mm           // calculated if omitted
```

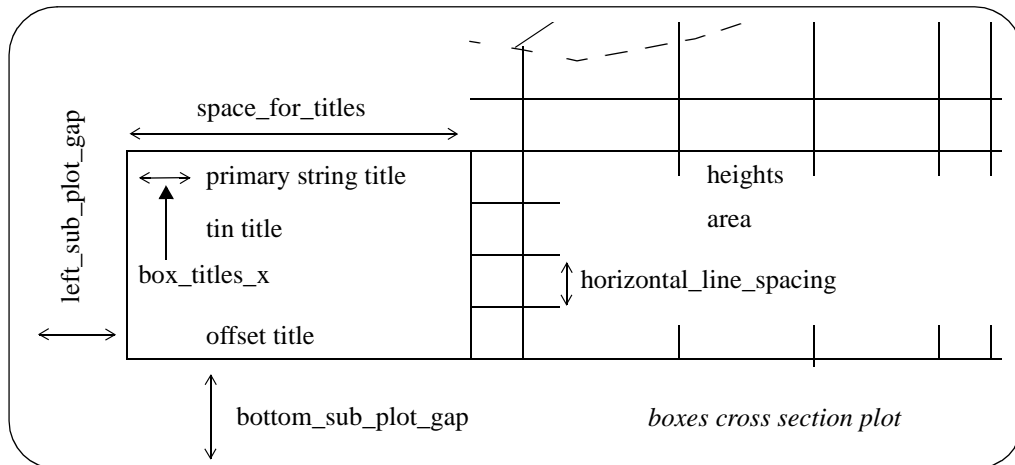

The total height of the boxes area is simply given by number of boxes drawn multiplied by the height of one box (they all have the same height).

The **width** of the heights area is determined by the number of chainages to be labelled and whether the values are staggered to prevent over writing.

Hence the total width of the boxes area is the width of the labels area plus the width of the

heights area.

Many distance definitions in the plot parameter file are given in terms of distance above the **top** of the boxes area.

The text in the title area is the same for each cross section plot on the sheet so it is possible to restrict the title area to be only on the first cross section on the sheet or the first column of cross sections.

label_first_only	0	//title area on all x-sections (default)
	1	// title area on first x-sect of page only
	2	// title area on x-sects in first column

The drawing of the box line work is user defined. This has been extended from V3.1 although *draw_box_mode* has been left in for forward compatibility.

draw_box_mode	0	// don't draw box lines
	1	// draw box lines around heights area // only
	2	// draw box lines around title and // heights areas
	3	// use draw_box_side_n, // box_line_draw_mode and // box_line_mode_n

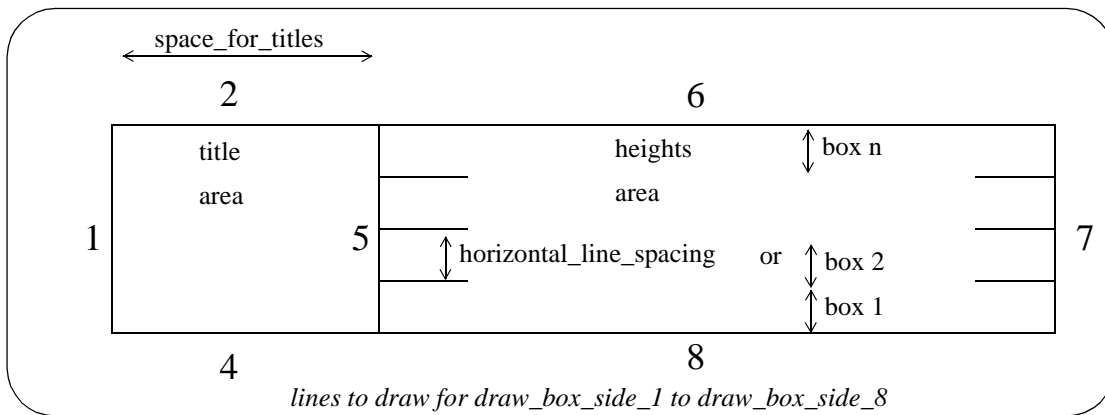

box_colour	colour	// colour of the boxes
------------	--------	------------------------

For V3.2, the line work for the outside of the title and heights boxes is controlled by the parameters *draw_box_side_n* and *box_side_colour_n*, and the separation lines inside the boxes are controlled by the parameters *box_line_draw_mode* and *box_line_mode_n* where the box numbering, n, starts from the bottom box.

Note: The following parameters are only used if *draw_box_mode* is set to **3**.

draw_box_side_1	1	// draw the left side of the title area (def)
	0	// don't draw the left side
box_side_colour_1	colour	// colour to draw left side of title area // default box_colour
draw_box_side_2	1	// draw top of the title area (default)
	0	// don't draw the top
box_side_colour_2	colour	// colour to draw top of title area // default box_colour
draw_box_side_4	1	// draw bottom of the title area (default)

	0	// don't draw the bottom
box_side_colour_4	colour	// colour to draw bottom of title area
		// default box_colour
draw_box_side_5	1	// draw left side of the heights area (def)
	0	// don't draw the left side
box_side_colour_5	colour	// colour to draw left side of heights area
		// default box_colour
draw_box_side_6	1	// draw top of the heights area (default)
	0	// don't draw the top
box_side_colour_6	colour	// colour to draw top of heights area
		// default box_colour
draw_box_side_7	1	// draw right side of the heights area def
	0	// don't draw the right side
box_side_colour_7	colour	// colour for right side of heights area
		// default box_colour
draw_box_side_8	1	// draw bottom of the heights area (def)
	0	// don't draw the bottom
box_side_colour_8	colour	// colour for bottom of heights area
		// default box_colour

The lines at the top of the individual boxes inside the title area and heights area (separation lines) are controlled by the parameters *box_line_draw_mode* and *box_line_mode_n*.

The separation lines can be drawn just in the title area, just in the heights area or in both areas.

The parameter *box_line_draw_mode* can be set to control all the separation lines but there are additional parameters, *box_line_mode_n*, which override *box_line_draw_mode* for each of the individual boxes where n = 1, ... number of boxes -1.

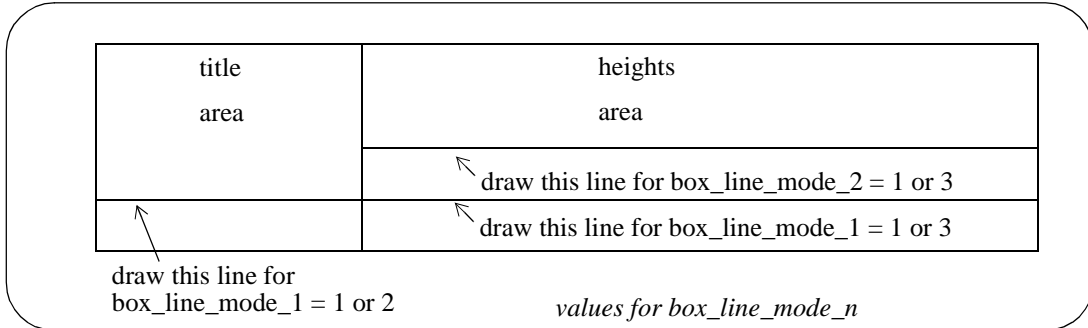

The top of the top box is not controlled by *box_line_mode_n* but is controlled by the parameters *draw_box_side_2* and *draw_box_side_6*.

box_line_draw_mode	0	// don't draw any separation lines inside
		// the title and heights areas
	1	// draw the separation lines inside the
		// title and heights areas (default)
	2	// draw the separation lines inside the
		// title area only
	3	// draw the separation lines inside the
		// heights area only
box_line_mode_n	0	// for the nth box, don't draw any
		// line at the top of the box for either
		// the title or the heights areas
	1	// for the nth box, draw the line at the
		// top of the box for both the

```

// title and heights areas
2 // for the nth box, draw the line at the
// top of the box for the title area only
3 // for the nth box, draw the line at the
// top of the box for the heights area only

```

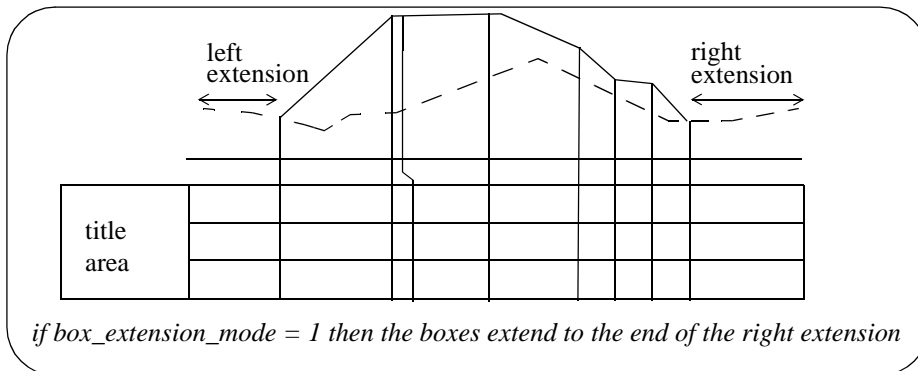

Finally, the right hand end of the boxes can stop at the end of the design x-section or extend to the end of the *right_extension* distance.

```

box_extension_mode    0 // default - stop right end of boxes at the
// end of design x-section
1 // extend right end of boxes to the end of
// the right_extension distance.

```

Offset Titles and Values

If the *label_type* is set to boxes, the offsets of the points across the primary string (usually the design cross section) are always labelled.

```

offset_title          text          // first line of offset title (def offsets)
offset_title_2       text          // second line of offset title
offset_title_textstyle textstyle   // textstyle for offset title
offset_title_colour  colour       // offset title text colour
offset_title_size    mm           // offset title text size
offset_colour        colour       // colour of offset values
offset_textstyle     textstyle    // textstyle for offset values
offset_size          mm           // size for offset values

```

Example of Offset Titles Parameters

```

// offset titles and values
offset_title      "Offset"
offset_title_2    "metres"
offset_title_colour grey

```

Primary String Titles and Heights

Sometimes the primary string (the design cross section) is only required to define the offset positions to label and the section line for the tin sections. In this case, the primary string would not be drawn on the cross section plot.

The drawing or not drawing of the primary string on each cross section plot is controlled by the parameter *primary_string*.

If the primary string is drawn, by default a row of labelling is included in the boxes area with up to two lines of title information and heights for each point across the cross section.

```

primary_string      yes          // draw and label the primary string
                   no           // don't draw or label the primary string

primary_title       text        // first line of string title
primary_title_2     text        // second line of string title
primary_title_textstyle textstyle // textstyle for primary string titles
primary_title_colour colour     // colour of the string titles
primary_title_size  mm          // primary title text size
primary_textstyle   textstyle   // textstyle for primary string heights
primary_title_y_pos mm          // if set, the height in mm above the
                               // bottom of all the boxes that the
                               // primary title text is drawn.
                               // If not set, then the text is placed at a
                               // height that puts it inside the default
                               // box for the primary title.

primary_colour      colour     // colour of the primary string heights
primary_size        mm          // primary text size
primary_y_pos       mm          // if set, the height in mm above the
                               // bottom of all the boxes that the
                               // primary height text is drawn.
                               // If not set, then the text is placed at a
                               // height that puts it inside the default
                               // box for the primary height text.

primary_decimals    integer     // number of dec places in primary height
                               // < 0 to keep all trailing zeros

```

Example of Labelling Primary String Titles

```
primary_title          "Design"  
// primary_title_2    "primary2" // not being used - commented out  
primary_colour        "purple"  
primary_title_colour  "red"
```

Tin Titles, Heights and Depths

A section along the primary string through each tin on the section view is automatically drawn on the cross section plot, but the user can specify whether the tin heights and depths are labelled or not in the boxes area.

Hence although there may be a number of tins drawn on the section plot, not all of them need to be labelled or have their depths labelled.

The default order for labelling the tins and depths is the order that they were added to the view but it is possible to specify which tin is used for labelling each row of tin heights and depths by giving the tin name rather than just using the tin order on the section view.

In fact, it is possible to use **any tin** in the project to label a row, **not just those drawn** on the section view.

```
tin_n_name          text          // n=1, ... no of tins on the section view.
                               // use the tin called text to label the nth
                               // row of tin heights.
```

If a tin of the name given by ***tin_n_name*** does not exist, then the plot is not produced and an error message is given.

For the following parameters, *n* takes the value 1 to 100 and specifies that the parameter set applies to the *n*th tin on the section view or if *tin_n_name* is set, by the tin specified by *tin_n_name*.

```
tin_n_draw_mode    I              // draw the nth tin (default)
                  0              // don't draw the nth tin
tin_n_draw_colour  colour         // colour to draw the nth tin
                               // if omitted then use the tin colour

tin_n_label        I              // label the nth tin (default)
                  0              // don't label the nth tin

tin_n_title        text          // first line of nth tin title
tin_n_title_2      text          // second line of nth tin title
tin_n_title_textstyle  textstyle // textstyle for nth tin titles
tin_n_title_colour colour        // colour for nth tin titles
tin_n_title_size   mm           // size for nth tin titles
tin_n_title_y_pos  mm           // if set, the height in mm above the
                               // bottom of all the boxes that the
                               // tin title text is drawn.
                               // If not set, then the text is placed at a
                               // height that puts it inside the default
                               // box for the tin heights.

tin_n_decimals     integer        // number of dec places in tin height
                               // < 0 to keep all trailing zeros

tin_n_textstyle    textstyle      // textstyle of the tin heights
tin_n_colour       colour         // colour for heights and depths
tin_n_size         mm            // default nth tin's title size
tin_n_y_pos       mm            //if set, the height in mm above the
                               //bottom of all the boxes that the
                               // tin height text is drawn.
                               //If not set, then the text is placed at a
                               //height that puts it inside the default
                               // box for the tin heights.

tin_n_depth_label  1/0           // 1 to label, 0 don't label depths
tin_n_depth_title  text          // first line of tin depth title
tin_n_depth_title_2 text         // second line of tin depth title
tin_n_depth_title_textstyle textstyle // textstyle of the tin depth titles
```

```

tin_n_depth_title_colour    colour    // colour for titles of depths
tin_n_depth_title_size     mm        // size for title of depths
tin_n_depth_title_y_pos    mm        // if set, the height in mm above the
                                // bottom of all the boxes that the
                                // tin depth title text is drawn.
                                // If not set, then the text is placed at a
                                // height that puts it inside the default
                                // box for the tin heights.

tin_n_depth_decimals       integer    // number of dec places in tin height
                                // < 0 to keep all trailing zeros

tin_n_depth_textstyle      textstyle  // textstyle of the tin depths
tin_n_depth_colour         colour     // colour for depths
tin_n_depth_size           mm        // size for depths
tin_n_depth_y_pos         mm        // if set, the height in mm above the
                                // bottom of all the boxes that the
                                // tin depth text is drawn.
                                // If not set, then the text is placed at a
                                // height that puts it inside the default
                                // box for the tin heights.

```

Definition of Depth to a Tin or to Offset Strings

The depth from the primary string to a tin, at a particular offset is defined as

$$\mathbf{depth} = \text{tin height value} - \text{height of the primary string}$$

That is, the depth that the primary string is **below** the tin.

Before plotting, the value of depth is multiplied by either the *depth_positive_factor* or *depth_negative_factor*.

```

if (depth >= 0)  plotted_depth_value = depth * depth_positive_factor
if (depth < 0)   plotted_depth_value = depth * depth_negative_factor

```

Hence the definition of depth can be modified by the parameters:

```

depth_positive_factor    value    // multiplier for positive depths
depth_negative_factor    value    // multiplier for negative depths

```

For example, if the opposite sign is required for depth, that is,

$$\mathbf{depth} = \text{height of the primary string} - \text{tin height value}$$

simply set

```

depth_positive_factor    -1
depth_negative_factor    1

```

Example of Labelling Tins

```

// tin label 1 for on
//           0 for off

tin_1_label            1
tin_1_title            "Natural"
// tin_1_title_2      "Surface"
tin_1_colour           grey
tin_1_title_colour     red

```

tin_2_label	1
tin_2_title	“Water table”
tin_2_colour	grey
tin_2_title_colour	red

Labelling the Design Height, X and Y Co-ordinates and Tin Heights at Offset Zero

The values of the height and X and Y co-ordinates of the **primary string** (usually the design cross section) at the zero offset can be labelled. Note that zero offset is normally where the alignment string cuts the cross section.

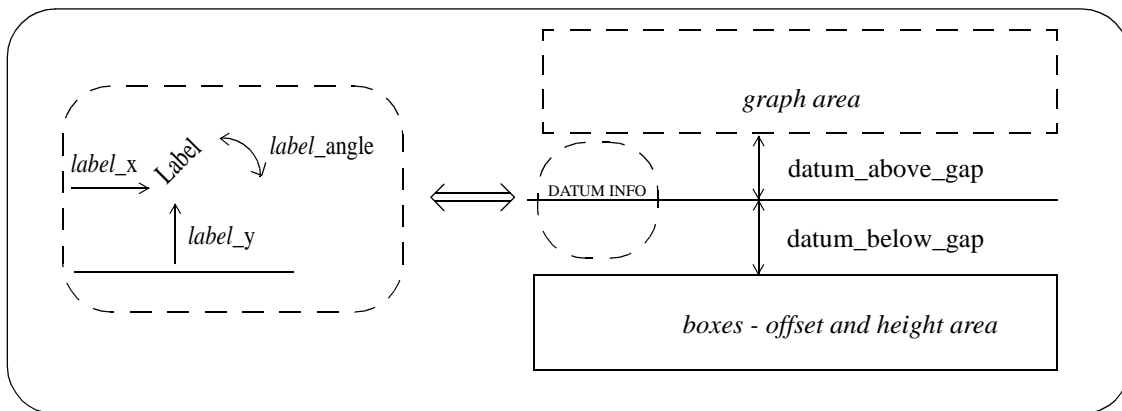

The heights of any tins (such as the natural surface) at the zero offset can also be labelled.

The labels are made up of:

pre_text value post_text

where *value* is either a height or a co-ordinate.

The label is positioned at either the left, right or middle of the datum line, with an x and y adjustment and a rotation.

Parameters for labelling the X Co-ordinate at Zero Offset:

primary_x0_draw_mode	0	// don't draw the label -default
	1	// draw the label
primary_x0_pre_text	text	// pre-text for label - def " "
primary_x0_post_text	text	// post-text for label - def " "
primary_x0_decimals	integer	// number of decimal places to display - def 1
		// If > 0, trailing zeros are removed after
		// the decimal point
		// If < 0, the absolute value is taken as the
		// number of decimal places to report
		// i.e. no trailing zeros are removed
primary_x0_x	mm	// x adjustment to position of label - def 0
primary_x0_y	mm	// y adjustment to position of label - def 0
primary_x0_angle	degrees	// angle of the label - def 0
primary_x0_colour	colour	// colour of the label
primary_x0_size	mm	// size (in mm) of the label
primary_x0_textstyle	textstyle	// textstyle of the label
primary_x0_justify	just	// justification for text

Parameters for Labelling the Y Co-ordinate at Zero Offset:

primary_y0_draw_mode	0	// don't draw the label -default
	1	// draw the label
primary_y0_pre_text	text	// pre-text for label - def " "

primary_y0_post_text	<i>text</i>	// post-text for label - def " "
primary_y0_decimals	<i>integer</i>	// number of decimal places to display - def 1 // If > 0, trailing zeros are removed after // the decimal point // If < 0, the absolute value is taken as the // number of decimal places to report // i.e. no trailing zeros are removed
primary_y0_x	<i>mm</i>	// x adjustment to position of label - def 0
primary_y0_y	<i>mm</i>	// y adjustment to position of label - def 0
primary_y0_angle	<i>degrees</i>	// angle of the label - def 0
primary_y0_colour	<i>colour</i>	// colour of the label
primary_y0_size	<i>mm</i>	// size (in mm) of the label
primary_y0_textstyle	<i>textstyle</i>	// textstyle of the label
primary_y0_justify	<i>just</i>	// justification for text

Parameters for Labelling the Height of Primary String at Zero Offset:

primary_height_draw_mode	<i>0</i>	// don't draw the label -default
	<i>1</i>	// draw the label
primary_height_pre_text	<i>text</i>	// pre-text for label - def " "
primary_height_post_text	<i>text</i>	// post-text for label - def " "
primary_height_decimals	<i>integer</i>	// number of decimal places to display - def 1 // If > 0, trailing zeros are removed after // the decimal point // If < 0, the absolute value is taken as the // number of decimal places to report // i.e. no trailing zeros are removed
primary_height_x	<i>mm</i>	// x adjustment to position of label - def 0
primary_height_y	<i>mm</i>	// y adjustment to position of label - def 0
primary_height_angle	<i>degrees</i>	// angle of the label - def 0
primary_height_colour	<i>colour</i>	// colour of the label
primary_height_size	<i>mm</i>	// size (in mm) of the label
primary_height_textstyle	<i>textstyle</i>	// textstyle of the label
primary_height_justify	<i>just</i>	// justification for text

Parameters for Placing Some Text:

extra_text_draw_mode	<i>0</i>	// don't draw the label -default
	<i>1</i>	// draw the label
extra_text_pre_text	<i>text</i>	// pre-text for label - def " "
extra_text_post_text	<i>text</i>	// post-text for label - def " "
extra_text_decimals	<i>integer</i>	// number of decimal places to display - def 1 // If > 0, trailing zeros are removed after // the decimal point // If < 0, the absolute value is taken as the // number of decimal places to report // i.e. no trailing zeros are removed
extra_text_x	<i>mm</i>	// x adjustment to position of label - def 0
extra_text_y	<i>mm</i>	// y adjustment to position of label - def 0
extra_text_angle	<i>degrees</i>	// angle of the label - def 0
extra_text_colour	<i>colour</i>	// colour of the label
extra_text_size	<i>mm</i>	// size (in mm) of the label
extra_text_textstyle	<i>textstyle</i>	// textstyle of the label
extra_text_justify	<i>just</i>	// justification for text

Offset Selection for Uprights and Staggering of Heights

For each sub-plot, the offsets of the points across the x-section string (primary string) are used for positioning uprights (leader lines), and the offset and height labels for the uprights.

By default, there is an upright at each point across the primary string.

However, if the primary string is a 4d string, then the text at the points on the 4d string can be used as a key to **suppress** the labelling and upright at that point.

The parameters to **stop** labelling and uprights are:

mask_name_n 4d_string_point_text where n=1,100

Note -the text 4d_string_point_text can include wild cards (*) and characters (?).

After any *name masks* have been applied, it is often desirable to weed out offset values that are too close together before doing any labelling.

```
offset_label_tolerance                      value                      // weed out offset values closer together
                                                    // (in offset units) than this value
```

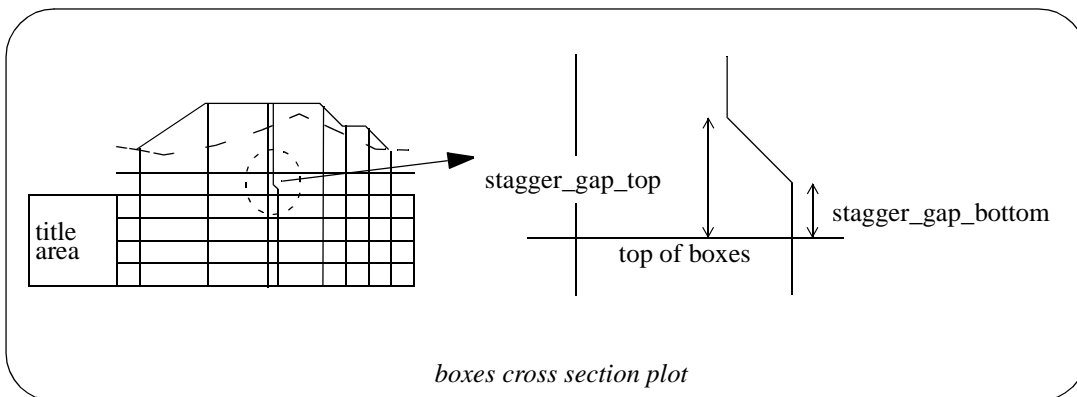

If the real offset position is used for the horizontal position of the offset/height text, text over writing can easily occur. To prevent over writing, the text is automatically **staggered**.

When staggering occurs, the real offset position is then indicated by the offset markers which are drawn at the top of the text boxes from the staggered text position back to the actual offset position of the text.

The size and position of the staggers are given by:

```
stagger_gap_top                      mm                      // distance from boxes to top of stagger
stagger_gap_bottom                      mm                      // distance from boxes to bottom of
                                                    // stagger
stagger_gap_factor                      value                      // distance between staggers is
                                                    // box_text_size * stagger_gap_factor
```

When staggering occurs, it is possible for the heights area to be wider than the graph area.

Uprights

Uprights (leader lines) can be drawn from the top of the staggers to strings drawn on the plot.

The height of the uprights is given by the ***uprights_draw_mode***:

<i>uprights_draw_mode</i>	0	// none
	1	// to maximum string height at that // chainage
	2	// ticks, to stagger height
	3	// to <i>uprights_y</i> above the boxes
	100	// to the primary string
	101-500	// to tin1 or tin2 etc.
<i>uprights_y</i>	<i>mm</i>	// distance to draw the uprights for // mode 3
<i>uprights_colour</i>	<i>colour</i>	// uprights colour (def boxes colour)

The uprights can go below the top of the boxes.

<i>uprights_bottom_mode</i>	0	// stop at top of boxes (default)
	1	// draw to bottom of boxes
	2	// draw to <i>uprights_bottom_y</i> below the // top of the boxes
	3	// draw to <i>uprights_bottom_y</i> above the // bottom of the boxes
	4	// ticks at chainage
<i>uprights_bottom_y</i>	<i>mm</i>	//distance
<i>uprights_text_offset_factor</i>	<i>value</i>	// move the text by this factor*size

When uprights go below the top of the boxes, the height and offset text is moved to the left so that the upright does not go through the text. The left hand side of the heights boxes also moves to the left to leave room for the height text.

Please continue to the next section "Graph Area" .

Graph Area

The **graph area** for each section sub-plot is the area where the actual plot of the x-section string is drawn.

The **width** of the graph area is determined by the width of the x-section string being plotted, the left and right extensions and horizontal scale (scale) given by parameters or in the **section x plot** panel, and the vertical exaggeration given by the section view or a parameter.

view_name	text	// default is section view in panel.
vertical_exaggeration	value	// default is vertical exag for view
scale	value	// 1:value - horizontal scale, default is // scale 1: in panel.
left_extension	world-units	// left extension value
right_extension	world-units	// right extension value

The vertical scale is determined by the horizontal scale and the vertical exaggeration.

The **height** of the graph area is determined by the vertical scale (given by the horizontal scale and the vertical exaggeration) and the minimum and maximum values of the data being plotted. Hence the graph height is a calculated rather than a given value.

The size of the graph area can also be extended to allow for symbols by the parameters:

extra_space_units	0	// extra space values are world units - default
	1	// " " " are millimetres on plot page
extra_space_left	units	// subtract from left of plot area, def 0
extra_space_right	units	// add to right of plot area, default 0
extra_space_top	units	// add to top of plot area, default 0
extra_space_bottom	units	// subtract from bottom of plot area, // default 0

The types of strings that are drawn in the graph area of a cross section plot are:

- primary string the x-section string from the x-section model that is being drawn.
Called the primary string and is usually the design x-section.
- tins sections of the primary string through any tins either in models on the section view or in corridor models.
- services parts of strings (from either models on the section view or in corridor models) that cut the defined corridor.

The **colour** of the strings in the plot is the actual string colour for cases (a) and (c), and the colour of the tin used for the section in case (b).

Although all the strings are plotted, the plot parameter file can be used to select which ones are

labelled with heights.

Primary String (Design Cross Section)

The primary string (the design cross section) is used to define

- (a) the design cross section
- (b) the chainage of the section
- (c) the offset positions for labelling heights and drawing uprights
- (d) the section line used for sectioning through tins
- (e) the section line for defining the corridor for services

Although the primary string is used to set up most of the information for the cross section plot, it doesn't have to be drawn on the cross section.

The drawing or not drawing of the primary string on each cross section plot is controlled by the parameter *primary_string* which was described earlier.

The **colour** of the primary string in the plot is the actual primary string colour.

Tins

A section along the primary string through each tin on the specified section view is automatically drawn on the cross section plot.

The **colour** and **linestyle** of the tin section in the plot is the actual tin colour and tin linestyle.

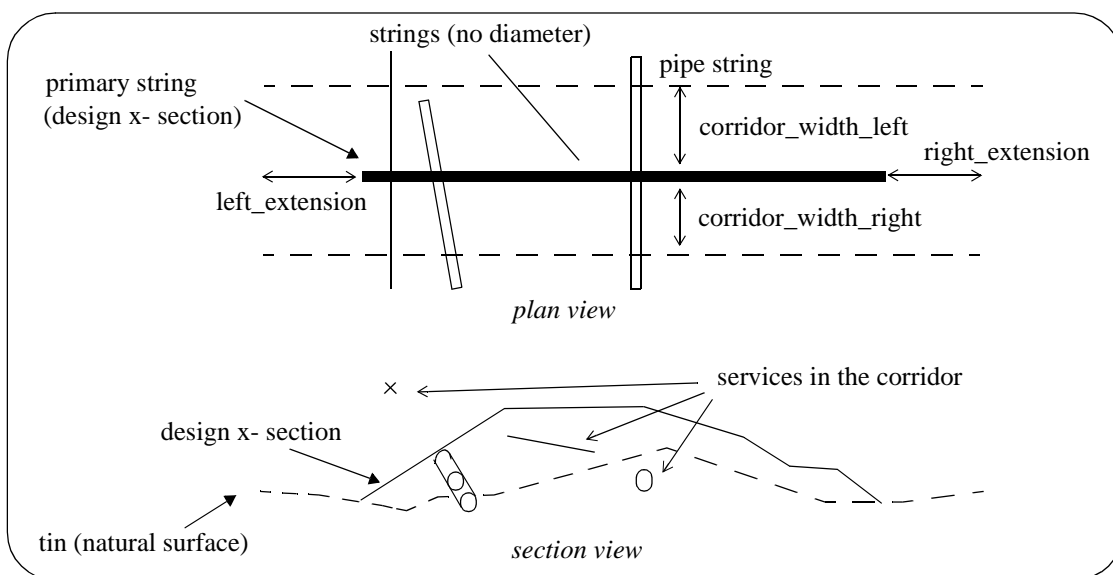

Whether the tin heights are labelled or not in the boxes area is controlled by parameters and has been described earlier

Corridor and Services

A corridor around the primary string is defined by giving a left and right corridor width and a left and right extension.

Any string in a model added to the section view is checked to see if it appears in the corridor, and if it does, then it is drawn on the cross section plot.

Strings do not have to cross the primary string, but just be in the corridor.

The corridor defining parameters are

```

left_extension      world-units      // left extension value
right_extension     world-units      // right extension value
corridor_width_left world-units      // corridor left and right widths
corridor_width_right world-units      // defaults are the section view values
corridor_overlap_left world-units      // corridor left and right overlaps.
corridor_overlap_right world-units      // defaults are the section view values
corridor_chord_arc  world-units      // chord-arc tolerance used to
// approximate arcs in the corridor.
// default is the section view value

```

The models containing tins for sectioning and strings for services are taken from the section view or given by the parameters

```

corridor_model_n    model          // n = 1, 2 ... 100
// models containing tins and service
// strings to be drawn on the view.

```

If any *corridor_model_n* parameters are defined, then only the models given by the parameters are used. If no *corridor_model_n* parameters are set, then the models added to the given section view are used.

That is, either the *corridor_model_n* parameters are used or if none exist, then the models added to the section view are used for tins and service strings.

The **colour** and **diameter** of the service strings drawn in the plot are the actual strings colour and diameter.

Please continue to the next section “Grade Labelling” .

Grade Labelling

The plot of the x-section string is made up of straight lines joining the individual points of the x-section.

The **grades** of these lines can be labelled:

```

grade_label        0          // don't label grades (default)
                   1          // label grades

```

Either the individual lines can be used as the segments to be labelled for grade, or adjacent lines of the same grade can be considered to be just one segment and labelled only once.

Hence the segments to be labelled for grade can be the individual lines of the x-section, or the segments defined by changes of grade.

```

grade_change_only  0          // label individual lines
                   1          // label change of grade segments

```

It is also possible to ignore segments smaller than a given minimum width on the plot.

```

grade_minimum_width mm          // segments smaller are not labelled

```

The grade labels are drawn parallel to the segment, centred about the segments end points, and a distance *grade_offset* above the segment. The size, colour and number of decimal places can all be set.

```

grade_decimals     integer      // number of decimal places in grade
grade_size         mm          // size of the grade label
grade_textstyle    text        // textstyle of the grade label
grade_colour       colour      // colour of the grade label
grade_offset       mm          // distance above the segment for label
grade_signed       yes         // default - grades are signed
                   no          // absolute value of grades

```

The grade can be labelled as percent cross-fall, 1 in slope, m/m or VicRoads x:1.

Also a threshold value can be set and any grades whose absolute value are below the threshold

can be labelled in one way, and those above the threshold labelled a different way.

Hence, if the absolute value of the grade is less than or equal to the absolute value of *grade_threshold*, then **grade_mode** is used, otherwise **grade_upper_mode** is used.

```

grade_mode          0          // % grade
                   1          // 1 in
                   2          // m/m
                   3          // VicRoads x:1
grade_threshold     value      // grade threshold for type of grade
                                // labelling
grade_threshold_mode 0-3      // type of grade value given in
                                // grade_threshold types are the same as
                                // grade_mode
grade_upper_mode    0          // % grade
                   1          // 1 in
                   2          // m/m
                   3          // VicRoads x:1
grade_upper_decimals integer  // number dec places in grades above
                                // threshold value

```

Example of Grade Labelling

```

grade_label        1          // turn grade labels on
grade_mode         0          // percent grade
grade_decimals     1          // one decimal place, no trailing zeros
grade_change_only  1          // only label when change of grade

// text size for grade annotations
grade_size        2
grade_colour      yellow

// how far the annotation is (perpendicularly)
// from the string itself
grade_offset      1

// label all annotations separated by more than
// the minimum width in plot units
grade_minimum_width 0

// threshold and threshold mode describe the value
// at which the grade labelling changes
// mode to grade_upper_mode
grade_threshold    7          // change labelling when over 7%
grade_threshold_mode 0       // units for threshold - %
grade_upper_mode   1          // label as 1:x

```

Please continue to the next section “Labelling Points of the X-Sections” .

Labelling Points of the X-Sections

The points across each x-section can be automatically labelled on the x-section plots.

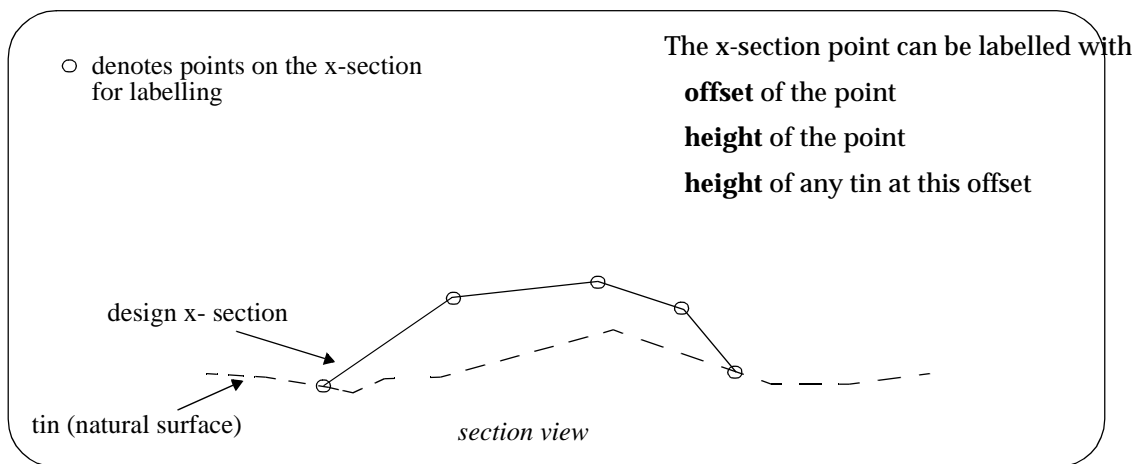

The **height**, **offset** and **name** of the point can be labelled as well as a **symbol** drawn. The height of tins at the same offset value can also be labelled.

The offset position for the labelling is the offset of the point.

The height position for the labelling can be specified as the

- (a) top of the boxes for the x-section
- (b) above the maximum height of the strings on the plot
- (c) height of the point on the x-section string (primary string)
- (d) height of a tin.

The actual position of the label is defined relative to the above point.

Note:

Only case (b) involves the actual height of the point on the cross section string. For all other cases, only the offset of the cut string is used.

Other heights, for example, the height of the tin at that offset can be used as the height (case (d)).

Text justification refers to the actual position and is given by

- | | | |
|---------------|-----------------|----------------|
| “top-left” | “top-centre” | “top-right” |
| “middle-left” | “middle-centre” | “middle-right” |
| “bottom-left” | “bottom-centre” | “bottom-right” |

A choice of six special symbols and/or any of the 12d symbols can be drawn at the cut point.

The special **12d** Model symbols of size one millimetre are drawn in a square box centred on (0,0) with sides of length two millimetres. That is, the box co-ordinates are (-1,-1), (1,1), (1,-1), (-1,-1).

The six special shapes are

Up to twenty five (25) separate sets of points can be labelled.

Parameters for Labelling Points of X-Sections

The points of the x-section to be for labelled for the nth set of parameters is restricted to all the points whose name satisfying the *points_n_mask*:

`points_n_mask` *point_names* // points to be labelled

where *point_names* is a text string containing the name masks, each separated by one or more spaces, to test the point name against. Each mask can include wild cards and wild characters.

For example

```

                                points_1_mask            "ke*"
or                               points_1_mask            "?bank*"
or, if both masks are required,
                                points_1_mask            "ke* ?bank*"
    
```

The parameters for drawing a **symbol** are

```

points_symbol_n_mode            0            // cross
                                1            // up from centre of box
                                2            // up and down from centre of box
                                3            // square
                                4            // triangle, base at bottom
                                5            //circle
                                6            // use a 12d symbol
    
```

If *points_symbol_n_mode* is 6, then the plot symbol is given by

```

points_symbol_n_style    plotsymbol    // name of the 12d symbol to draw at
point
    
```

Important Note

The plot symbol of name *plotsymbol* is defined in the file given by:

- (a) the parameter *plot_symbols* in the ppf file

```

plot_symbols            filename
    
```

or if *plot_symbols* is not defined, then

- (b) in the file pointed to by the environment variable `PLOT_SYMBOLS_4D`
`PLOT_SYMBOLS_4D` *filename* // default *plotsym.4d*

or if `PLOT_SYMBOLS_4D` is not defined, then

- (c) in the file *plotsym.4d*
 which is searched for in the standard set up file sequence

If none of the above files are defined, or if the symbol does not exist in the above files, then it will be searched for in the standard 12d symbols file which is:

- (d) either pointed to by the environment variable `SYMBOLS_4D`
`SYMBOLS_4D` *filename* // default *symbols.4d*

or if the environment variable `SYMBOLS_4D` does not exist, in the file, *symbols.4d*

The position of the symbol is given by:

points_symbol_n_position	1	// above point height value
	3	// above top of boxes
	4	// above top of graph area but not including // the extra_space_top
	100	// to primary string (same as 1)
	101-500	// to tin1 or tin2 etc.

The symbol can be adjusted by the parameters:

points_symbol_n_x	mm	// offset adjustment to position
points_symbol_n_y	mm	// height adjustment to position
points_symbol_n_angle	degrees	// rotation about point
points_symbol_n_colour	colour	// colour of symbol

and for all values of *points_symbol_n_mode* **other** than 6:

points_symbol_n_size	mm	// size of symbol, 0 don't draw
----------------------	----	---------------------------------

The value of the **offset** of the point can be labelled using the parameters

points_offset_n_position	1	// above point height value
	3	// above top of boxes
	4	// above top of graph area but not including // the extra_space_top
	100	// to primary string
	101-500	// to tin1 or tin2 etc.
points_offset_n_x	mm	// offset adjustment to position
points_offset_n_y	mm	// height adjustment to position
points_offset_n_angle	degrees	// rotation about point
points_offset_n_size	mm	// size of text, 0 don't label
points_offset_n_colour	colour	// colour of text
points_offset_n_textstyle	textstyle	// textstyle to use for points offset text.
points_offset_n_pre_text	text	// text before the offset value
points_offset_n_post_text	text	// text after the offset value
points_offset_n_justification	justification	// justification of the text
points_offset_n_no_decimals	integer	// number of decimals in offset

The value of a **height** at the offset of the point can be calculated and labelled using the parameters

points_height_n_mode	1	// use height of point itself
	3	// use real world height of position // above boxes
	100	// height of primary string (same as 1)
	101-500	// use height of to tin1 or tin2 etc.
points_height_n_position	1	// at points position
	3	// above top of boxes
	4	// above top of graph area but not including // the extra_space_top
	100	// to primary string (same as 1)
	101-500	// to tin1 or tin2 etc.
points_height_n_x	mm	// offset adjustment to position
points_height_n_y	mm	// height adjustment to position
points_height_n_angle	degrees	// rotation about point
points_height_n_size	mm	// size of text, 0 don't label
points_height_n_colour	colour	// colour of text
points_height_n_textstyle	textstyle	// textstyle to use for points height text.

points_height_n_pre_text	<i>text</i>	// text before the height value
points_height_n_post_text	<i>text</i>	// text after the height value
points_height_n_justification	<i>justification</i>	// justification of the text
points_height_n_no_decimals	<i>integer</i>	// number of decimals in height

A **label** which can include the **name** of the point is drawn by using the parameters

points_label_n_position	<i>1</i>	// at the points position
	<i>3</i>	// above top of boxes
	<i>4</i>	// above top of graph area but not including // the extra_space_top
	<i>100</i>	// to primary string (same as 1)
	<i>101-500</i>	// to tin1 or tin2 etc.
points_label_n_mode	<i>0</i>	// don't include point name
	<i>1</i>	// include point name in label
points_label_n_x	<i>mm</i>	// offset adjustment to position
points_label_n_y	<i>mm</i>	// height adjustment to position
points_label_n_angle	<i>degrees</i>	// rotation about point
points_label_n_size	<i>mm</i>	// size of text, 0 don't label
points_label_n_colour	<i>colour</i>	// colour of text
points_label_n_textstyle	<i>textstyle</i>	// textstyle to use for points label text.
points_label_n_pre_text	<i>text</i>	// text before the point name
points_label_n_post_text	<i>text</i>	// text after the point name
points_label_n_justification	<i>justification</i>	// justification of the text

Please continue to the next section "Labelling Cuts of X-Sections Through Strings in a Model" .

Labelling Cuts of X-Sections Through Strings in a Model

The cuts that each x-section string makes through any strings in user given models can be automatically labelled on the x-section plots.

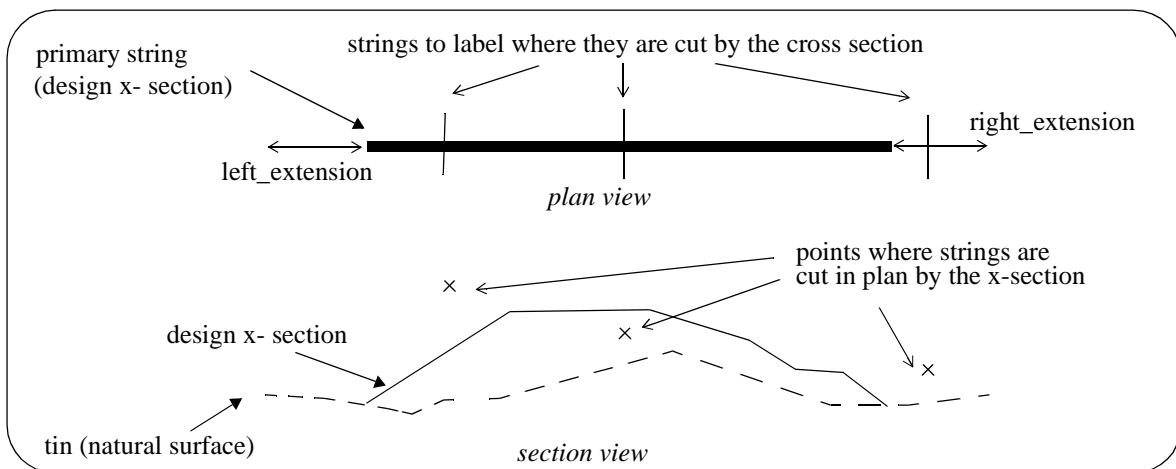

The **height**, **offset** and **name** of the cut string can be labelled as well as a **symbol** drawn. The height of tins at the same offset value can also be labelled.

The offset position for the labelling is the offset of the cut string.

The height position for the labelling can be specified as the

- top of the boxes on the x-section
- above the maximum height of the strings on the plot
- height value of the cut string
- height of the x-section string (the primary string)
- height of a tin.

The actual position of the label is defined relative to the above point.

Note:

Only case (b) involves the actual height of the cut string. For all other cases, only the offset of the cut string is used. Hence for all cases except (b), the string does need to have a sensible height to be used for cuts through strings.

For example, a boundary string may have null heights but only the offset is required and the height of the tin at that offset can be used as the height (case (d)).

Text justification refers to the actual position and is given by

“top-left”	“top-centre”	“top-right”
“middle-left”	“middle-centre”	“middle-right”
“bottom-left”	“bottom-centre”	“bottom-right”

A choice of six special symbols and/or or any 12d symbols can be drawn at the cut point.

The special **12d** Model symbols of size one millimetre are drawn in a square box centred on (0,0) with sides of length two millimetres. That is, the box co-ordinates are (-1,-1), (1,1), (1,-1), (-1,-1).

The six special shapes are

Up to twenty five (25) separate models of strings can be cut and labelled.

Parameters for Labelling Cuts of X-Sections Through Strings in a Model

The method for specifying which strings are to be checked for cuts is by first specifying the **model** which contains the strings, and then a **name mask** which is used to restrict the strings in the model to only those whose name matches the name mask.

Up to twenty five different sets of models and name masks can be used so that different cut sets can be labelled in different ways.

The parameters for selecting and labelling the *n*th set (where *n* can be from 1 to 25) of cuts of the x-sections with the strings in the model are given by:

```
cuts_n_model          model_name          // model of strings to be cut
```

The selection of the strings from the model *model_name* whose cut points are to be labelled is all the strings whose name satisfies the name mask *cuts_n_mask*:

```
cuts_n_mask          name_mask          // strings to check for cuts
                                     // and if a cut occurs,
                                     // parameters show how to
                                     // label the cut
```

where *name_mask* is a text string containing the name masks, each separated by one or more spaces, to test the string name against. Each mask can include wild cards and wild characters.

For example

```
cuts_1_mask          "ke*"
or
cuts_1_mask          "?bank*"
or, if both masks are required,
cuts_1_mask          "ke* ?bank*"
```

If *cuts_n_mask* is missing, then all strings in the model are used. This is equivalent to *name_mask* being "*".

All strings in the model *cuts_n_model* whose name satisfy the name mask *cuts_n_mask* are then checked for cuts with the x-sections, and if a cut occurs, the cut point will be labelled according to the rest of the parameters in the *n*th set.

The parameters for drawing a **symbol** at the cut points are:

```
cuts_symbol_n_mode   0          // cross
                    1          // up from centre of box
                    2          // up and down from centre of box
                    3          // square
                    4          // triangle, base at bottom
                    5          // circle
                    6          // use a 12d symbol
```

If *cuts_symbol_n_mode* is 6, then the plot symbol is given by

```
cuts_symbol_n_style  plotsymbol        // 12d symbol to draw at cut
```

Important Note

The plot symbol of name *plotsymbol* is defined in the file given by:

- (a) the parameter *plot_symbols* in the ppf file

```
plot_symbols          filename
```

or if `plot_symbols` is not defined, then

(b) in the file pointed to by the environment variable `PLOT_SYMBOLS_4D`
`PLOT_SYMBOLS_4D filename // default plotsym.4d`

or if `PLOT_SYMBOLS_4D` is not defined, then

(c) in the file `plotsym.4d`
 which is searched for in the standard set up file sequence

If none of the above files are defined, or if the symbol does not exist in the above files, then it will be searched for in the standard 12d symbols file which is:

(d) either pointed to by the environment variable `SYMBOLS_4D`
`SYMBOLS_4D filename // default symbols.4d`
 or if the environment variable `SYMBOLS_4D` does not exist, in the file, `symbols.4d`

The position of the symbol is given by:

<code>cuts_symbol_n_position</code>	1	// above point height value
	3	// above top of boxes
	4	// above top of graph area but not including // the <code>extra_space_top</code>
	100	// to primary string
	101-500	// to tin1 or tin2 etc.

The symbol can be adjusted by the parameters:

<code>cuts_symbol_n_x</code>	<i>mm</i>	// offset adjustment to position
<code>cuts_symbol_n_y</code>	<i>mm</i>	// height adjustment to position
<code>cuts_symbol_n_angle</code>	<i>degrees</i>	// rotation about point
<code>cuts_symbol_n_colour</code>	<i>colour</i>	// colour of symbol

and for all values of `cuts_symbol_n_mode` **other** than 6:

<code>cuts_symbol_n_size</code>	<i>mm</i>	// size of symbol, 0 don't draw
---------------------------------	-----------	---------------------------------

The value of the **offset** of the cut string can be labelled using the parameters

<code>cuts_offset_n_position</code>	1	// above cut strings height value
	3	// above top of boxes
	4	// above top of graph area but not including // the <code>extra_space_top</code>
	100	// to primary string
	101-500	// to tin1 or tin2 etc.
<code>cuts_offset_n_x</code>	<i>mm</i>	// offset adjustment to position
<code>cuts_offset_n_y</code>	<i>mm</i>	// height adjustment to position
<code>cuts_offset_n_angle</code>	<i>degrees</i>	// rotation about point
<code>cuts_offset_n_size</code>	<i>mm</i>	// size of text, 0 don't label
<code>cuts_offset_n_colour</code>	<i>colour</i>	// colour of text
<code>cuts_offset_n_textstyle</code>	<i>textstyle</i>	// textstyle to use for cuts offset text.
<code>cuts_offset_n_pre_text</code>	<i>text</i>	// text before the offset value
<code>cuts_offset_n_post_text</code>	<i>text</i>	// text after the offset value
<code>cuts_offset_n_justification</code>	<i>justification</i>	// justification of the text
<code>cuts_offset_n_no_decimals</code>	<i>integer</i>	// number of decimals in offset

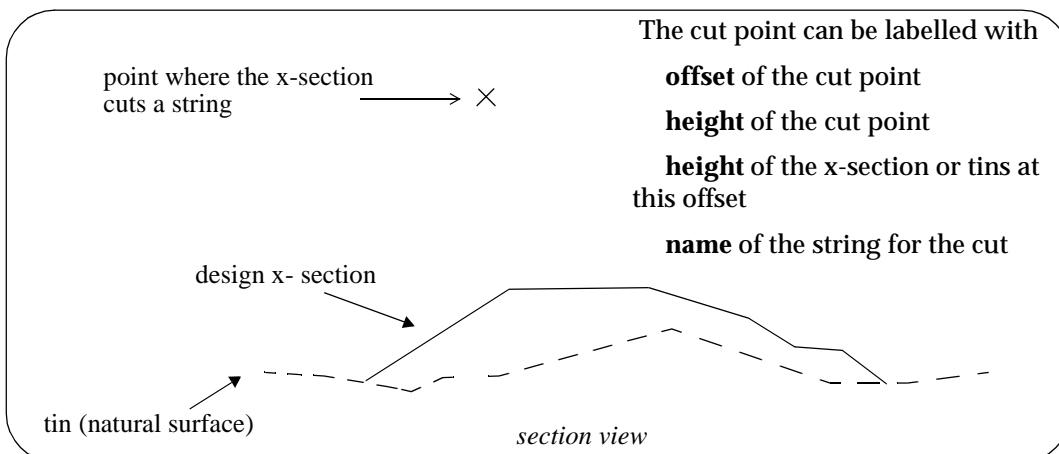

The value of a **height** at the offset of the point can be calculated and labelled using the parameters

<code>cuts_height_n_mode</code>	1	// use height of cut point itself
	3	// use real world height of position // above boxes

	100	// height of primary string
	101-500	// use height of to tin1 or tin2 etc.
cuts_height_n_position	1	// at points position
	3	// above top of boxes
	4	// above top of graph area but not including // the extra_space_top
	100	// to primary string
	101-500	// to tin1 or tin2 etc.
cuts_height_n_x	mm	// offset adjustment to position
cuts_height_n_y	mm	// height adjustment to position
cuts_height_n_angle	degrees	// rotation about point
cuts_height_n_size	mm	// size of text, 0 don't label
cuts_height_n_colour	colour	// colour of text
cuts_height_n_textstyle	textstyle	// textstyle to use for cuts heights text.
cuts_height_n_pre_text	text	// text before the height value
cuts_height_n_post_text	text	// text after the height value
cuts_height_n_justification	justification	// justification of the text
cuts_height_n_no_decimals	integer	// number of decimals in height

A **label** which can include the **name** of the cut string is drawn by using the parameters:

cuts_label_n_position	1	// above cut strings height value
	3	// above top of boxes
	4	// above top of graph area but not including // the extra_space_top
	100	// to primary string
	101-500	// to tin1 or tin2 etc.
cuts_label_n_mode	0	// don't include cut string name
	1	// include cut string name in label
cuts_label_n_x	mm	// offset adjustment to position
cuts_label_n_y	mm	// height adjustment to position
cuts_label_n_angle	degrees	// rotation about point
cuts_label_n_size	mm	// size of text, 0 don't label
cuts_label_n_colour	colour	// colour of text
cuts_label_n_textstyle	textstyle	// textstyle to use for cuts label text.
cuts_label_n_pre_text	text	// text before the string name
cuts_label_n_post_text	text	// text after the string name
cuts_label_n_justification	justification	// justification of the text

Please continue to the next section "Hatching Cut and Fill Areas" .

Hatching Cut and Fill Areas

This option is used to hatch cut and/or fill areas between sets of tins.

For each set, the name of the two tins, the hatch linestyle, colour and separation and whether cut and/or fill regions are required are all user definable.

Up to twenty (20) separate sets of tins be hatched.

The parameters for labelling cuts and/or fill regions between tins are given by:

<code>hatch_original_tin_n</code>	<code>tin_name</code>	// tin_name for original surface
<code>hatch_new_tin_n</code>	<code>tin_name</code>	// tin_name for final surface
<code>hatch_cut_separation_n</code>	<code>mm</code>	// distance between cut hatch lines
	0	// don't do cut hatching
<code>hatch_cut_angle_n</code>	<code>degrees</code>	// angle in degrees of cut hatching
<code>hatch_cut_colour_n</code>	<code>colour</code>	// colour of the cut hatching
<code>hatch_cut_linestyle_n</code>	<code>linestyle</code>	// linestyle for cut hatching
<code>hatch_cut_draw_sides_n</code>	1/0	// 1 = draw sides of cut regions
<code>hatch_cut_draw_original_n</code>	1/0	// 1 = draw original tin in cut regions
<code>hatch_cut_draw_new_n</code>	1/0	// 1 = draw new tin in cut regions
<code>hatch_fill_separation_n</code>	<code>mm</code>	// distance between fill hatch line
	0	// don't do fill hatching
<code>hatch_fill_angle_n</code>	<code>degrees</code>	// angle in degrees of fill hatching
<code>hatch_fill_colour_n</code>	<code>colour</code>	// colour of the fill hatching
<code>hatch_fill_linestyle_n</code>	<code>linestyle</code>	// linestyle for fill hatching
<code>hatch_fill_draw_sides_n</code>	1/0	// 1 = draw sides of fill regions
<code>hatch_fill_draw_original_n</code>	1/0	// 1 = draw original tin in fill regions
<code>hatch_fill_draw_new_n</code>	1/0	// 1 = draw new tin in fill regions

Notes

- (a) cut is when the new tin is below the original tin.
fill is when the new tin is above the original tin.
- (b) cut hatching is turned off by setting `hatch_cut_separation_n` to 0.0.
fill hatching is turned off by setting `hatch_fill_separation_n` to 0.0.

Please continue to the next section "Extra Models of X-Sections" .

Extra Models of X-Sections

The order and centreline chainages of the x-section subplots for the x-section plot are defined by the sections from the primary model of cross sections.

The sections through any specified triangulations and service models, and offsets for labelling are fully defined by these primary x-sections.

However it is also possible to plot extra x-sections on each of the sub-plots by supplying extra models of x-sections which are at the same plan positions as the primary x-section strings.

Only those x-sections from the extra models that are within a user specified tolerance of a primary x-section are plotted.

The extra models of x-sections and the plan tolerance for checking that the extra cross-sections are the same position as the primary x-sections are

```
extra_model_tolerance_1      value                // tolerance in 12d Model units
extra_model_n                model_name        // where n=1, ... 100
                           // extra models of x-sections
```

The actual colour of the extra x-sections is used as their plotting colour.

Please continue to the next section “Sorting X-Sections by Chainage” .

Sorting X-Sections by Chainage

The chainage on the design string that the x-section is created at is stored with the cross-section.

When the x-sections are created by the apply functions, they are created in the order of increasing chainage and added to the *model for sections* in that order.

Hence if the cross sections are plotted, the natural order would be in increasing chainage order.

However, it is possible to upset the order in the model by manually adding in extra sections.

Hence there is a parameter in both the **section x plot** panel and the plot parameter file to ensure that the cross sections are sorted in increasing chainage order before they are plotted.

```
sort_sections                1                // sort sections by design chainage
                           0                // use order of sections in model
```

Please continue to the next section “Title Block Information” .

Title Block Information

The plot can have a standard 12d Model title block or a user defined title block.

The standard title block consists of a simple border around the plot and two lines of text in a box underneath the plot. For a user defined title block, all the line work and text is defined by the user.

Standard Title Block

For the standard 12d Model title block, there are extra parameters for two lines of text and text size and colour. The standard title block is turned on or off by the parameter *plot_border*.

<i>plot_border</i>	<i>yes/no</i>	<i>// yes plots a standard title block</i> <i>// default yes</i>
<i>title_1</i>	<i>text</i>	
<i>title_2</i>	<i>text</i>	
<i>title_text_size</i>	<i>value</i>	
<i>title_colour</i>	<i>colour</i>	

User Title Block

For the user defined title block, the title block drawing commands are kept in a file whose name is supplied by the user. The title block drawing commands are almost identical to the linestyle drawing commands and is given at the beginning of this chapter.

Hence for a user defined title block, there are just two parameters - one to say a title block file is being used and the other to give the name of the title block file. The *plot_border* parameter should also be set to *no* so that the standard title block is not also drawn.

<i>use_title_file</i>	<i>yes/no</i>	<i>// yes draws the title block given in title_file</i> <i>// default no</i>
<i>title_file</i>	<i>filename</i>	
<i>plot_border</i>	<i>no</i>	<i>// turn off standard title block</i>

Some special plot parameters are used to pass information down to variables in a user defined title block. For example, inside the title block file it is possible to have runtime user defined text variables. The actual text values for these text variables are passed down to the title block file from the plot parameter file via the parameters *user_text_n* ($n = 1, 2, \dots, 1000$)

<i>user_text_n</i>		<i>text</i>
--------------------	--	-------------

The special plot parameters are:

<i>time_format</i>	<i>text</i>	<i>// format for \$time</i>
<i>user_text_n</i>	<i>text</i>	<i>// where n = 1, 2, ... 1000</i> <i>// passed down to \$user_text_n</i>
<i>title_1</i>	<i>text</i>	<i>// passed down to \$title_1</i>
<i>title_2</i>	<i>text</i>	<i>// passed down to \$title_2</i>
<i>start_page_number</i>	<i>integer</i>	<i>// used as the starting value for</i> <i>// \$page_number. If missing,</i> <i>// \$page_number starts at 1.</i>
<i>start_drawing_number</i>	<i>integer</i>	<i>// added to \$drawing_number in title</i> <i>// block file. If missing,</i> <i>// \$drawing_number starts at 1.</i>
<i>drawing_number_prefix</i>	<i>text</i>	<i>// passed down to</i> <i>// \$drawing_number_prefix</i>
<i>drawing_number_postfix</i>	<i>text</i>	<i>// passed down to</i> <i>// \$drawing_number_postfix</i>

Please continue to the next section "Parameters that Modify Fields In the Cross Plot Panel".

Parameters that Modify Fields In the Cross Plot Panel

A number of parameters match those in the **section x plot** panel.

When the plot parameter file is first read, any parameters in the panel will be replaced by the values of any corresponding parameters in the parameter file.

However, if the parameter is subsequently modified in the panel, the panel value will be the value used for any plots.

The plot parameters that also occur in the **section x plot** panel are:

view_name	<i>text</i>
plotter_type	<i>text</i>
model_to_plot	<i>text</i>
plot_stem	<i>text</i>
start_chainage	<i>chainage</i>
end_chainage	<i>chainage</i>
sheet_size	<i>text</i> or “width height”
scale	<i>value</i>
absolute_extensions	<i>yes/no</i>
left_extension	<i>world-units</i>
right_extension	<i>world-units</i>
line_up_cl	<i>yes/no</i>
primary_string	<i>yes/no</i>
label_type	<i>yes/no</i>
box_colour	<i>colour</i>
text_size	<i>mm</i>
sort_sections	<i>yes/no</i>
use_title_file	<i>yes/no</i>
title_file	<i>filename</i>
plot_border	<i>yes/no</i>
title_1	<i>text</i>
title_2	<i>text</i>
title_text_size	<i>value</i>
title_colour	<i>colour</i>
global_textstyle	<i>textstyle</i>

Please continue to the next section “Generating Cross Section Plots Without a View” .

Generating Cross Section Plots Without a View

The cross section plot parameters are comprehensive enough that it is possible to completely generate a cross section plot without referencing a section view, or even using the **section X plot** panel.

Such a ppf can be run using the **plots=>plot a ppf** option or from the 4D Solutions programming language, 4DL.

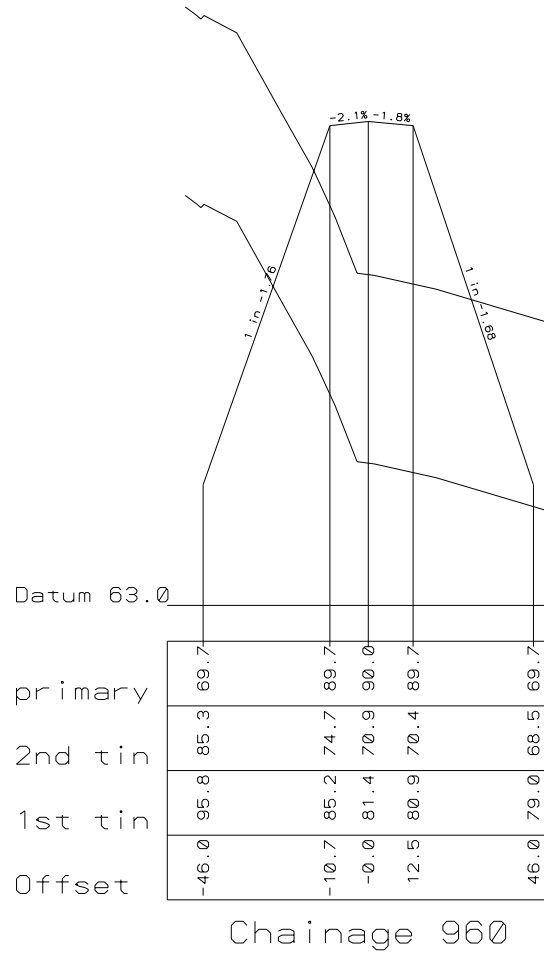

When generating a cross section plot using the **section X plot** panel, a plot parameter file containing all the parameters needed to regenerate the plot using **plots=>plot a ppf** can be written out by simply giving a name for the ppf file in the plot parameters write field of the **section X plot** panel.

Notes

1. A warning is given if the keyword in a plot parameter file does not exist.
2. A warning is also given if the key word pair is defined more than once in a ppf.

Please continue to the next section “Example of a Cross Section Plot Parameter File” .

Example of a Cross Section Plot Parameter File

```

// ppf file to generate x-section example
section_x_plot "plot 2" {

// plot margins
left_margin          0.0

```

Long Section Plot Parameter File

The long section plot parameters are placed in a file with ending **.ppf**

Each parameter consists of a parameter name followed by one or more spaces and then the parameter value. There is only one parameter per line.

Anything on a line after a double forward slash // is considered to be a comment.

The set of all parameters for the long section plot is enclosed within a set of curly brackets { } with the header

```
section_long_plot "plot set name"
```

before the curly brackets.

That is,

```
section_long_plot "plot set name" {
    plot parameters
    one per line
}
```

If there is more than one section_long_plot parameter set in the file, only the first set is used.

There may also be parameter sets for other plot types such as section_x_plot in the same file. The other sets will be ignored when doing a long section plot.

The plot parameters are documented in following groups:

For *Defining chainage range*, go to the section "Possible Chainage Range" .

Breaking the plot into pages, go to the section "Pagination" .

Plot Sheet layout, go to the section "Plot Sheet Layout" .

Boxes area, go to the section "Boxes Area" .

Defining chainages and staggering, go to the section "Chainage Selection and Staggering" .

Defining uprights, go to the section "Uprights" .

Datum area, go to the section "Datum Area" .

Graph (drawing) area, go to the section "Graph Area" .

Defining bubbles, go to the section "Bubbles Definitions" .

Quick HG, go to the section "Quick Horizontal Geometry Labelling" .

Extensive HG, go to the section "Extensive Horizontal Geometry Labelling" .

Quick VG, go to the section "Quick Vertical Geometry Labelling" .

Extensive VG, go to the section "Extensive Vertical Geometry Labelling" .

Labelling heights, go to the section "Labelling Chainages and Heights in the Graph Area" .

Symbols, go to the section "Labelling With Symbols" .

Hatching cut/fill, go to the section "Hatching Cut and Fill Areas" .

Labelling cuts, go to the section "Labelling Cuts of Design Through Strings in a Model" .

Labelling string name, go to the section "Labelling the Primary String Name on the Plot" .

Labelling with scale, go to the section "Labelling the Scale on the Plot" .

Title block information, please continue to the section "Title Block Information" .

Panel modifying parameters, please continue to the section "Parameters that Modify Fields In the Long Plot Panel" .

Example, please continue to the section "Example of a Long Section Plot Parameter File" .

Possible Chainage Range

In the panel, the field **Use HG VG for min, max** determines whether the horizontal geometry (HG) and the vertical geometry (VG) are both used to determine the minimum and maximum chainages for drawing. This allows the vertical geometry to be plotted when it is outside the horizontal geometry (e.g. kerb returns).

The equivalent parameter in the ppf is

```
use_vg_hg_for_min_max      1           // the chainage range available for plotting
                               // is from the minimum of the horizontal
                               // geometry (HG) and the vertical geometry
                               // (VG) to the maximum of the HG and VG.
                               // This is useful for kerb returns
                               0           // the chainage range available for
                               // plotting is from the minimum of the
                               // horizontal geometry (HG) to the
                               // maximum of the HG.
```

Pagination

If the long section plot is too long to fit on one page, it can be broken into a number of pages (sheets).

The parameter, *pagination_length*, controls the amount of new chainage length on each plot page. Each page of the long section plot can also included a set chainage amount from the end of the **previous** plot.

Hence apart from the first page and possibly the last page, the plot will have a chainage length given by the sum of the *pagination_length* and *pagination_overlap*.

```
pagination                 yes/no      // if yes, then break the plot into pages
pagination_mode            chainage // length and overlap in chainage units
                               millimetre // length and overlap in millimetres
pagination_length          chainage or  // new chainage range on each page
                               millimetres
pagination_overlap         chainage or  // overlap between pages
                               millimetres
```

Note

The *pagination_length* and *pagination_overlap* are given in chainage units or millimetres. The user must choose values which will fit on the selected sheet size or the end of each plot will be truncated by the sheet.

Plot Sheet Layout

The plot **page** or **sheet** is considered to have only positive co-ordinates with the origin (0,0) in the left hand corner. The units for the plot are millimetres.

The overall size of the plot sheet is given by either a defined sheet size, or by the width and height of the plot given in millimetres and separated by one or more spaces.

```
sheet_size                 text           // sheet name, or
                               "mm mm"        // sheet size: width height
```

The sheet size name and width and heights can be specified by the user in a file named sheets.4d which is in the normal set up areas, or is pointed to by the environment variable

```
SHEET_SIZES_4D           file           // file of plotter sheets sizes
```

The plotting area is restricted to within the plot sheet by giving margins which are:

If a *User Defined Title Block* is used:

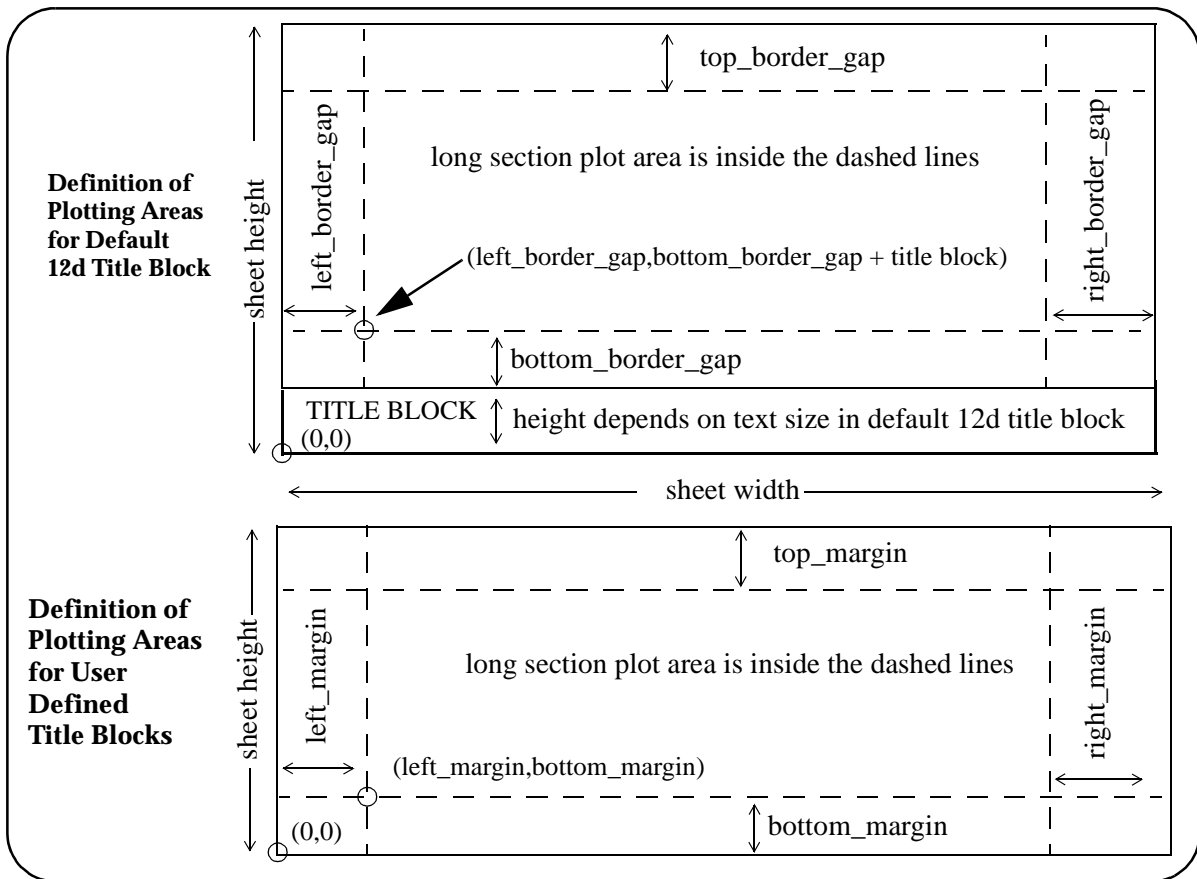

```
left_margin               mm
right_margin              mm
top_margin                mm
```

bottom_margin mm

If the *default 12d title block* is used, then the size of the bottom of title block depends on the text size. The following parameters are used in the default title block case and the *bottom_border_gap* is added to the calculated height of the bottom of the title block.

left_border_gap mm
 right_border_gap mm
 top_border_gap mm
 bottom_border_gap mm

Because the user can easily select from the plotting panel whether a User Defined Title Block or the default 12d title block is used, both sets of margins and gap parameters can exist in the one plot parameter file.

The long plot itself consists of the three regions - boxes, datum and graph areas.

The **boxes area** is where the titles and the chainage values and the heights/depths for the strings drawn on the long plot are labelled.

The **datum area** is the region between the boxes area and the graph area.

The **graph area** is the area where the actual plots of the strings are drawn.

Apart from information labelled in the boxes area, the long section plot can label other information such as

- (a) horizontal geometry
- (b) vertical geometry
- (c) chainage, heights at special points

- (d) symbols at special points
- (e) bubbles at special chainages
- (f) cuts the design string makes through strings
- (g) cut and fill areas

The size of the graph area can also be extended to allow for plot symbols by the parameters:

extra_space_units	0	// extra space values are world units - default
	1	// " " are millimetres on plot page
extra_space_left	units	// subtract from left of plot area, def 0
extra_space_right	units	// add to right of plot area, default 0
extra_space_top	units	// add to top of plot area, default 0
extra_space_bottom	units	// subtract from bottom of plot area, default 0

Please continue to the next section "Boxes Area" .

Boxes Area

Each string in the long section plot can be labelled with one or two lines of title, and the chainages/heights/depths at the user specified chainages for the strings.

The **title** for the strings, is drawn in the **title area** of the **boxes area**.

The **chainages/heights/depths** are drawn in the **heights area** of the **boxes area**.

Consequently the boxes area is made up of rows of text consisting of:

string/tin titles followed by the **chainage/height/depth** values along the string.

Each row is surrounded by lines to form a box.

The default order of the boxes from the bottom up is

- (a) optional super-elevation diagram
- (b) chainage values
- (c) can be primary string heights - user choice
- (d) tin heights and depths
- (e) offset heights and depths
- (f) optional volumes or earth works
- (g) can be primary string heights - user choice
- (h) zero or more blank boxes

The blank boxes are used to place other information in (such as horizontal or vertical geometry) or for other user supplied information.

Placing the primary string label before the bank boxes or just after the chainage box is controlled by the parameter *primary_label_mode*.

```

number_of_blank_boxes      integer           // integer > 0
primary_label_mode         0                   //put primary string labels in last box
                             // before blank boxes
                             1                   // or first box above the chainages

```

Although the order of the boxes may appear to be fixed, in practice they can be in any order. This is possible because for each box, there is a parameter to set the height in millimetres from the bottom of all the boxes that the text in the box is drawn at (the *_y_pos* parameters).

The **title area** starts at the co-ordinate (left_margin,bottom_margin).

The size of the title text is given by the **title_box_text_size** parameter.

The **width** of the title area is either given by the *space_for_titles* parameter, or if omitted, the required width is automatically calculated.

```

title_box_text_size      mm          // size of the title text for boxes
space_for_titles        mm          // calculated if omitted

```

There can be two lines of title text and the title text, textstyle and colour can be set independently for each box.

The x position of the title text is the same for all the lines of title text and can be set to be a fixed distance from the left hand side of the boxes.

```

box_titles_x            mm          // distance to move the title text from the
                                // left hand side of the boxes

```

The y position of the title text can be set separately for each type of title. The parameters are given later under each of the title types (e.g. chainages, primary string, tins, depths etc.).

After the title area there can be a user defined gap, followed by the heights area

```

box_gap                mm          // blank area between the title area
                                // and the heights area default 0

```

The **heights area** starts at the end of the title area.

The height text is written at right angles to the bottom of the boxes. It can be either top or bottom justified with respect to the box (*box_text_justification*).

The number of decimal places (*number_of_decimals*), and the size of the heights text (*box_text_size*) can be specified globally but there is a parameter for each box which overrides these defaults for each box of heights.

```

box_text_justification  0          // bottom of individual boxes
                        1          // top of individual boxes

number_of_decimals     integer    // number of decimal places in the
                                // height boxes. If <0, the absolute value
                                // is taken as the number of decimal
                                // places i.e. no trailing zeros are
                                // removed for the values in the heights
                                // area.

box_text_size          mm          // size of the height text values

```

A global height for the individual boxes is either given by the *horizontal_line_spacing* parameter, or if omitted, a height to fit the largest height or depth value is calculated and used as the default box height.

```

horizontal_line_spacing mm          // calculated if omitted

```

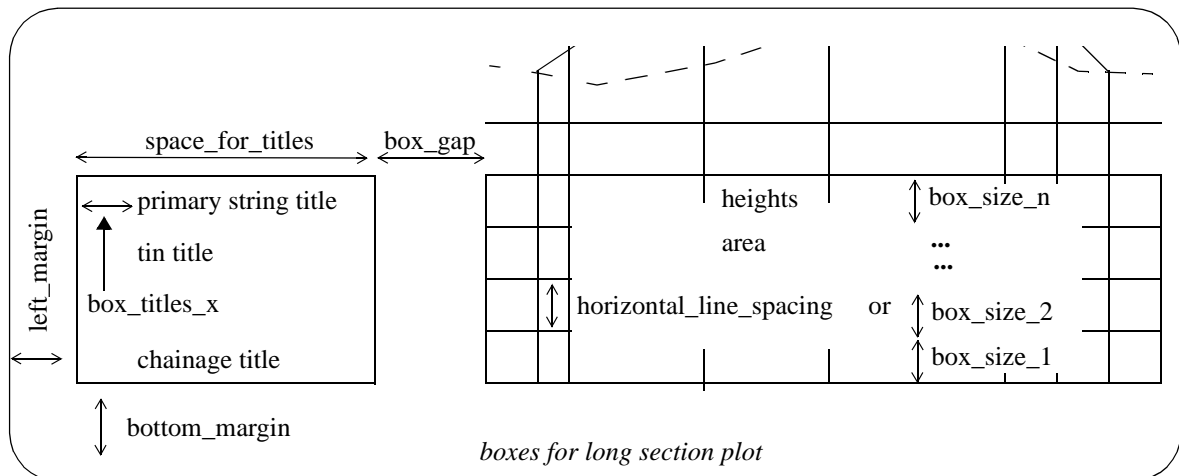

However, the height of each box can be individually set by parameters *box_size_n* where the boxing numbering, n, starts from the bottom box. The value of *horizontal_line_spacing* is used for any of the *box_size_n* parameters not specified.

```

box_size_n             mm          // height of the nth box, numbered from
                                // bottom up.

```

The total height of the boxes area is simply given by the sum of the heights of each box.

The **width** of the **heights area** is determined by the number of chainages to be labelled and whether the values are staggered to prevent over writing.

Hence the total width of the boxes area is the width of the **title area** plus **box_gap**, plus the width of the **heights area**.

Many distance definitions in the plot parameter file are given in terms of distance above the **top** of the boxes area so that the distances are independent of the number of boxes and box sizes.

The drawing of the box line work, the box colour, the position of the primary string labels and the number of blank boxes are all set by parameters.

First, all the line work for the box itself is user defined. This has been extended from V3.1 although *draw_box_mode* has been left in for upward compatibility.

```

draw_box_mode          0           // don't draw box lines
                      1           // draw box lines around heights area
                      // only
                      2           // draw box lines around title and
                      // heights areas
                      3           // use draw_box_side_n,
                      // box_line_draw_mode and
                      // box_line_mode_n

box_colour             colour      // colour of the boxes

```

For V3.2, the line work for the outside of the title and heights boxes is controlled by the parameters *draw_box_side_n* and *box_side_colour_n*, and the separation lines inside the boxes are controlled by the parameters *box_line_draw_mode* and *box_line_mode_n* where the box numbering, n, starts from the bottom box.

Note: The following parameters are only used if *draw_box_mode* is set to 3.

```

draw_box_side_1       1           // draw the left side of the title area (def)
                      0           // don't draw the left side
box_side_colour_1     colour      // colour to draw left side of title area
                      // default box_colour
draw_box_side_2       1           // draw top of the title area (default)
                      0           // don't draw the top
box_side_colour_2     colour      // colour to draw top of title area
                      // default box_colour
draw_box_side_3       1           // draw right side of the title area

```

		// (default if box_gap is non-zero)
	0	// don't draw the right side
		// (default if box_gap is zero)
box_side_colour_3	colour	// colour to draw right side of title area
		// default box_colour
draw_box_side_4	1	// draw bottom of the title area (default)
	0	// don't draw the bottom
box_side_colour_4	colour	// colour to draw bottom of title area
		// default box_colour
draw_box_side_5	1	// draw left side of the heights area (def)
	0	// don't draw the left side
box_side_colour_5	colour	// colour to draw left side of heights area
		// default box_colour
draw_box_side_6	1	// draw top of the heights area (default)
	0	// don't draw the top
box_side_colour_6	colour	// colour to draw top of heights area
		// default box_colour
draw_box_side_7	1	// draw right side of the heights area def
	0	// don't draw the right side
box_side_colour_7	colour	// colour for right side of heights area
		// default box_colour
draw_box_side_8	1	// draw bottom of the heights area (def)
	0	// don't draw the bottom
box_side_colour_8	colour	// colour for bottom of heights area
		// default box_colour

The lines at the top of the individual boxes inside the title area and heights area (separation lines) are controlled by the parameters *box_line_draw_mode* and *box_line_mode_n*.

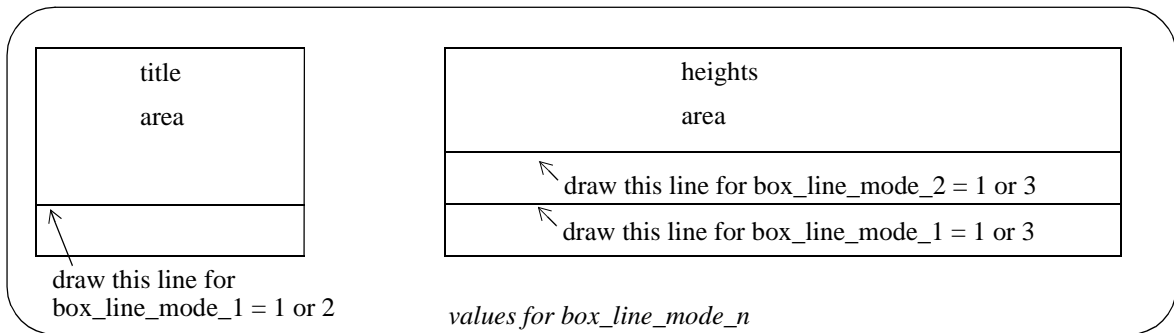

The separation lines can be drawn in just the title area, just the heights area or in both areas.

The parameter *box_line_draw_mode* can be set to control all the separation lines but there are additional parameters, *box_line_mode_n*, which override *box_line_draw_mode* for each of the individual boxes where n = 1, ... number of boxes - 1.

The top of the top box is not controlled by *box_line_mode_n* but is controlled by the parameters *draw_box_side_2* and *draw_box_side_6*.

box_line_draw_mode	0	// don't draw any separation lines inside
		// the title and heights areas
	1	// draw the separation lines inside the
		// title and heights areas (default)
	2	// draw the separation lines inside the
		// title area only

	3	// draw the separation lines inside the // heights area only
box_line_mode_n	0	// for the nth box, don't draw any // line at the top of the box for either // the title or the heights areas
	1	// for the nth box, draw the line at the // top of the box for both the // title and heights areas
	2	// for the nth box, draw the line at the // top of the box for the title area only
	3	// for the nth box, draw the line at the // top of the box for the heights area only

Chainage Titles and Values

The chainages are always labelled

chainage_title	<i>text</i>	// first line of chainage title // (default chainages)
chainage_title_2	<i>text</i>	// second line of chainage title
chainage_title_textstyle	<i>textstyle</i>	// textstyle of the chainage titles
chainage_title_colour	<i>colour</i>	// default chainage title colour
chainage_title_size	<i>mm</i>	// default chainage title size
chainage_title_y_pos	<i>mm</i>	// if set, the height in mm above the // bottom of all the boxes that the // chainage title text is drawn. // If not set, then the text is placed at a // height that puts it inside the default // box for the chainage.
chainage_decimals	<i>integer</i>	// number of decim places for chainages
chainage_textstyle	<i>textstyle</i>	// textstyle of the chainage values
chainage_colour	<i>colour</i>	// colour of chainages, def is box_colour
chainage_size	<i>mm</i>	// size of chainages, def is box_text_size
chainage_y_pos	<i>mm</i>	// if set, the height in mm above the // bottom of all the boxes that the // chainage values text is drawn. // If not set, then the text is placed at a // height that puts it inside the default // box for the chainage.

Example of Chainage Titles

chainage_title	"DESIGN"
chainage_title_2	"CHAINAGE"

```
chainage_title_colour    "yellow"  
chainage_colour         "grey"           // colour of chainage text  
chainage_decimals       -3              // 3 decimal places - leave trailing zeros
```

Primary String Title and Heights

Sometimes the primary string is only required to define chainages or the horizontal path for tin sections. In this case, the primary string would not be drawn on the long section plot.

If the primary string is drawn, it is automatically labelled.

Also the drawing of crosses at the vertical intersection points can be controlled from the ppf file.

```
primary_draw_vips      1           // draw crosses at VIPS (default)
                       0           // don't draw VIP crosses
```

The position of the primary string label box can be either straight after the chainage box, or after the tin and offset boxes but before the blank boxes.

```
primary_string         yes           // draw and label the primary string
                       no           // don't draw or label the primary string

primary_label_mode     0           // last box before blank boxes
                       1           // first box above the chainages

primary_title          text         // first line of string title
primary_title_2        text         // second line of string title, default is
                                   // the primary string name.
primary_title_textstyle textstyle   // textstyle of the primary string titles
primary_title_colour   colour       // colour of the string titles
primary_title_size     mm           // default primary title size
primary_title_y_pos    mm           // if set, the height in mm above the
                                   // bottom of all the boxes that the
                                   // primary string title text is drawn.
                                   // If not set, then the text is placed at a
                                   // height that puts it inside the default
                                   // box for the primary string.

primary_decimals       integer      // number of decimal places
primary_textstyle      textstyle    // textstyle of the primary string heights
primary_colour         colour       // colour of the heights
primary_size           mm           // default primary value size
primary_y_pos          mm           // if set, the height in mm above the
                                   // bottom of all the boxes that the
                                   // primary string height text is drawn.
                                   // If not set, then the text is placed at a
                                   // height that puts it inside the default
                                   // box for the primary string.

primary_ch_tolerance   mm           // for a given chainage, if no z value exists,
                                   // this distance is added to/subtracted from the
                                   // chainage to search for a valid z value.
```

Example of Primary String Titles

```
primary_title          "DESIGN"
primary_title_2        "CENTRELINE"
primary_title_colour   "yellow"
primary_colour         "grey"       // colour of height text
primary_decimals       -2           // 2 decimal places - leave trailing zeros
```

Tin Titles and Heights

A section along the primary string through each tin on the section view can be automatically drawn on the long plot, and the user can specify whether the tin heights and depths are labelled or not in the boxes area.

Hence although there may be a number of tins drawn on the section plot, not all of them need to be labelled or have their depths labelled.

The default order for labelling the tins and depths is the order that the tins were added to the view however it is possible to specify which tin is used for labelling each row of tin heights and depths by giving the tin name rather than just using the tin order on the section view.

In fact, it is possible to use **any tin** in the project to label a row, **not just those drawn** on the section view.

The parameter to define the nth tin by name is *tin_n_name*:

```
tin_n_name          text          // n=1, ... no of tins on the section view.
                               // use the tin named text to label the nth
                               // row of tin heights and depths.
```

If a tin of the name *tin_n_name* does not exist, then the plot is not produced and an error message is given.

For the following parameters, n takes the value 1 to 100 and specifies that the parameter set applies to the nth tin on the section view, or if *tin_n_name* is set, for the tin specified by *tin_n_name*.

```
tin_n_draw_mode      1          // draw the nth tin (default)
                    0          // don't draw the nth tin
tin_n_draw_colour    colour     // colour to draw the nth tin.
                               // If omitted, then use the tin colour
tin_n_label          1          //label the tin's heights (default)
                    0          // don't label the tin's heights

tin_n_title          text       // first line of tin title
tin_n_title_2        text       // second line of tin title
tin_n_title_textstyle textstyle // textstyle of the tin titles
tin_n_title_colour    colour     // colour for titles of heights
tin_n_title_size      mm        // default nth tin's title size
tin_n_title_y_pos    mm        // if set, the height in mm above the
                               // bottom of all the boxes that the
                               // tin title text is drawn.
                               // If not set, then the text is placed at a
                               // height that puts it inside the default
                               // box for the tin heights.

tin_n_decimals        integer   // number of dec places in tin height
tin_n_textstyle       textstyle // textstyle of the tin heights
tin_n_colour          colour     // colour for heights and depths
tin_n_size            mm        // default nth tin's title size
tin_n_y_pos           mm        //if set, the height in mm above the
                               //bottom of all the boxes that the
                               // tin height text is drawn.
                               //If not set, then the text is placed at a
                               //height that puts it inside the default
                               // box for the tin heights.

tin_n_depth_label    1/0        // 1 to label, 0 don't label depths
tin_n_depth_title     text       // first line of tin depth title
tin_n_depth_title_2   text       // second line of tin depth title
tin_n_depth_title_textstyle textstyle // textstyle of the tin depth titles
tin_n_depth_title_colour colour // colour for titles of depths
tin_n_depth_title_size colour // size for title of depths
```

<code>tin_n_depth_title_y_pos</code>	<code>mm</code>	// if set, the height in mm above the // bottom of all the boxes that the // tin depth title text is drawn. // If not set, then the text is placed at a // height that puts it inside the default // box for the tin depths.
<code>tin_n_depth_decimals</code>	<code>integer</code>	// number of dec places in tin depth
<code>tin_n_depth_textstyle</code>	<code>textstyle</code>	// textstyle of the tin depths
<code>tin_n_depth_colour</code>	<code>colour</code>	// colour for depths
<code>tin_n_depth_size</code>	<code>mm</code>	// size for depths
<code>tin_n_depth_y_pos</code>	<code>mm</code>	// if set, the height in mm above the // bottom of all the boxes that the // tin depth text is drawn. // If not set, then the text is placed at a // height that puts it inside the default // box for the tin depths.

Offset Model Titles and Heights

For **12d** Model V3.2, Each string in the offset model given in the **section long plot** panel can be automatically projected onto the primary string and drawn on the long section plot.

For **12d Model V4.0**, the idea of an offset model has been modified to allow strings to be projected onto the primary string to be specified by model and name, rather than just projecting all the strings in a given model. The string can also be labelled with either the string name, its model name or both.

The string is specified by

```
offset_n_mask          "model_name->string_name"
```

For each n, a set of plot parameters determine if the string's heights and/or depths from the primary string are labelled in the boxes area.

If only the *string_name* is given, then the model given in the Offset model field of the **Section Long Plot** panel.

If there is **more than one string** with the given model and name, then it will be considered to be one string and at any primary string chainage, the closest of the strings will be the part used for projecting. For example, strings of the same name on either side of a road intersection will be considered to be the one string for projecting.

If any *offset_n_mask* is used, then the Offset option expects all the strings to be specified by an *offset_n_mask*. Then if no mask exists for any value of n, then that parameter set is ignored and no string projected.

If no offset masks are used (that is, no *offset_n_mask*'s are used), then the Offset option works as it did in **12d** Model V3.0. That is, plot parameters determine whether each string in the offset model is drawn, and if the string's heights and depths from the primary string are labelled in the boxes area. The order that the strings are then plotted and labelled is the same as the order of the strings in the Offset model.

For the following sets of parameters, n takes the value 1 to 100 and specifies that the parameter set applies to the nth string given by *offset_n_mask* or, if no offset masks are given, the nth string in the *Offset model*.

```
offset_n_mask          "model_name->string_name"
offset_n_draw_mode     1          // draw the nth offset string (default)
                       0          // don't draw the nth offset string
offset_n_lw            value     // default 1000. Distance to search to the left
                               // of the primary string for the offset string.
```

		// If 0, don't search to the left.
offset_n_rw	<i>value</i>	// default 1000. Distance to search to the right // of the primary string for the offset string. // If 0, don't search to the right.
offset_n_draw_colour	<i>colour</i>	// colour to draw the nth offset string. // If omitted, then use the string colour
offset_n_label	<i>1</i> <i>0</i>	//label the string's heights (default) // don't label the string's heights

The default title for each set each parameter set, is the string name but this can be changed to just the model name or the model and string name:

offset_title_mode	<i>0</i> <i>1</i> <i>2</i>	// label with string name (default) // label with model name // label with model->string as name
-------------------	----------------------------------	--

or, for any set, the *offset_title_mode* can be replaced by two lines of user defined title:

offset_n_title	<i>text</i>	// first line of title
offset_n_title_2	<i>text</i>	// second line of title
offset_n_title_textstyle	<i>textstyle</i>	// textstyle of the offset titles

The rest of the parameters for the set are:

offset_n_title_colour	<i>colour</i>	// colour for titles of heights
offset_n_title_size	<i>size</i>	// colour for titles of heights
offset_n_title_y_pos	<i>mm</i>	// if set, the height in mm above the // bottom of all the boxes that the // offset title text is drawn. // If not set, then the text is placed at a // height that puts it inside the default // box for the offset heights.
offset_n_decimals	<i>integer</i>	// number of dec places in offset height
offset_n_textstyle	<i>textstyle</i>	// textstyle of the offset heights
offset_n_colour	<i>colour</i>	// colour for heights
offset_n_size	<i>size</i>	// size for heights
offset_n_y_pos	<i>mm</i>	// if set, the height in mm above the // bottom of all the boxes that the // offset height text is drawn. // If not set, then the text is placed at a // height that puts it inside the default // box for the offset heights.
offset_n_depth_label	<i>1/0</i>	// 1 to label, 0 don't label depths
offset_n_depth_title	<i>text</i>	// first line of offset depth title
offset_n_depth_title_2	<i>text</i>	// second line of offset depth title
offset_n_depth_title_textstyle	<i>textstyle</i>	// textstyle of the offset depth titles
offset_n_depth_title_colour	<i>colour</i>	// colour for titles of depths
offset_n_depth_title_size	<i>mm</i>	// size for titles of depths
offset_n_depth_title_y_pos	<i>mm</i>	// if set, the height in mm above the // bottom of all the boxes that the // offset depth title text is drawn. // If not set, then the text is placed at a // height that puts it inside the default // box for the offset depths.
offset_n_depth_decimals	<i>integer</i>	// number of dec places in offset depth
offset_n_depth_textstyle	<i>textstyle</i>	// textstyle of the offset depths

<code>offset_n_depth_colour</code>	<i>colour</i>	// colour for depths
<code>offset_n_size</code>	<i>size</i>	// size for depths
<code>offset_n_depth_y_pos</code>	<i>mm</i>	// if set, the height in mm above the // bottom of all the boxes that the // offset depth text is drawn. // If not set, then the text is placed at a // height that puts it inside the default // box for the offset depths.

Chainages of Offset Strings - Offset Chainages

For a string other than the primary string, it is possible to label the chainages that are obtained from the other string by going out perpendicular to the primary string at a chainage, cutting the other string and then calculating the chainage from the other string at the cut point.

The other string is known as an **offset** string and the chainage from the offset string corresponding to a primary chainage is called the **offset chainage**.

Up to twenty sets of offset chainages can be labelled - each is defined by its own set of parameters:

Note no box is automatically created for the offset chainages. An empty box must be defined and the appropriate values set for *chainage_n_title_y_pos* and *chainage_n_y_pos*

<i>chainage_n_offset_mode</i>	<i>tick box</i>	// if ticked, use nth offset string for calculations
<i>chainage_n_offset_string</i>	" <i>model_name->string_name</i> "	// string to calculate offset chainages for
<i>chainage_n_title</i>	<i>text</i>	// first line of offset chainage title
<i>chainage_n_title_2</i>	<i>text</i>	// second line of offset chainage title
<i>chainage_n_title_textstyle</i>	<i>textstyle</i>	// textstyle of the offset chainage titles
<i>chainage_n_title_colour</i>	<i>colour</i>	// offset chainage title colour
<i>chainage_n_title_size</i>	<i>mm</i>	// offset chainage title size
<i>chainage_n_title_y_pos</i>	<i>mm</i>	// the height in mm above the bottom of all the boxes that the offset chainage title text is drawn.
<i>chainage_n_decimals</i>	<i>integer</i>	// number of decim places for offset chainages
<i>chainage_n_textstyle</i>	<i>textstyle</i>	// textstyle of the offset chainage values
<i>chainage_n_colour</i>	<i>colour</i>	// colour of offset chainages
<i>chainage_n_size</i>	<i>mm</i>	// size of offset chainages
<i>chainage_n_y_pos</i>	<i>mm</i>	// the height in mm above the bottom of all the boxes that the chainage values text is drawn.

Example of Offset Chainage and Titles

<i>chainage_1__offset_string</i>	"Design->RKERB"	
<i>chainage_1__title</i>	"RIGHT KERB"	
<i>chainage_1_title_2</i>	"CHAINAGE"	
<i>chainage_1_title_colour</i>	"yellow"	
<i>chainage_1_colour</i>	"grey"	// colour of offset chainage text
<i>chainage_1_decimals</i>	-3	// 3 decimal places - leave trailing zeros

Definition of Depth to a Tin or to Offset Strings

The depth from the primary string to a tin or to a string from the offset model, at a particular chainage is defined as

$$\mathbf{depth} = \text{tin height value} - \text{height of the primary string}$$

or

$$\mathbf{depth} = \text{offset string height value} - \text{height of the primary string}$$

That is, the depth that the primary string is **below** the tin or a string from the offset model.

Before plotting, the value of depth is multiplied by either the *depth_positive_factor* or *depth_negative_factor*.

if (depth >= 0) plotted_depth_value = depth * depth_positive_factor

if (depth < 0) plotted_depth_value = depth * depth_negative_factor

Hence the definition of depth can be modified by the parameters:

```
depth_positive_factor    value    // multiplier for positive depths
depth_negative_factor    value    // multiplier for negative depths
```

For example, if the opposite sign is required for depth, that is,

$$\mathbf{depth} = \text{height of the primary string} - \text{tin/offset string height value}$$

simply set

```
depth_positive_factor    -1
depth_negative_factor    -1
```

Super-Elevation Diagram

The optional *super-elevation diagram* draws the values of the cross-fall (x-fall) between two strings using the primary string as the reference string. The cross-fall at a given chainage on the primary string is calculated by sectioning perpendicular to the reference string at that chainage and cutting the two strings. The cross-fall is defined as the cross-fall between the two cuts points on the strings.

The diagram has levels for the cross fall for a pair of strings on the left of the primary string, and a pair of strings on the right of the primary string. The diagram also has uprights in the super-elevation box with chainage values at the change of super values.

For the left hand side, the cross-fall is calculated at right angles to the primary string between the user given left hinge string and the left edge string.

There are plot parameters to control all aspects of the super diagram.

```

super_draw_mode          0           // default, don't draw a super diagram
                        1           // draw super using super_sample_interval
                        2           // sample super using chainages of x-sections
                        3           // sample super using chainages from a string
super_sample_interval    value       // if super_draw_mode = 1, default 20
                                // chainage distance to sample x-fall
super_sample_name        model_name  // if super_draw_mode = 2
                                model_name->string_name // if super_draw_mode = 3

super_tolerance          value       // If super_draw_mode is 1, the change
                                // of super is greater than super_tolerance,
                                // draw uprights

super_title              text        // first line of super title
                                // def Super elevation

super_title_textstyle    textstyle   // textstyle of the super titles
super_title_colour       colour      // super title colour, def box_colour
super_title_size         mm          // super title size, def label_text_size
super_title_y_pos        mm          // if set, the height in mm above the
                                // bottom of all the boxes that the
                                // super title text is drawn.
                                // If not set, then the text is placed at a
                                // height that puts it inside the default
                                // box for the super.

Volume Cut and Fill Values

The values of calculated cut and fill volumes (cut and fill earth works) can be read from a file and then interpolated to produce cut and fill volumes for a given interval along the primary string.

There are plot parameters to control all aspects of the volume diagram.

volume_draw_mode	0	// default, don't draw a volume diagram
	1	// draw a volume diagram
volume_text_centre_mode	0	// default, the text of cut and fill are labelled // along the uprights
	1	// the text are centred in between the uprights
volume_sample_interval	value	// interval to display volumes, default 20
volume_file_name	file_name	// the volumes report file
volume_y_pos	mm	// if set, the volume box is positioned at this // height from the bottom of the first box
volume_box_size	mm	// if set, the uprights and volume and titles // are plotted in accordance with this heights
volume_title	text	// first line of volume title // default <i>Earthworks</i>
volume_title_textstyle	textstyle	// textstyle of the volume titles
volume_title_colour	colour	// volume title colour, def box_colour
volume_title_size	mm	// volume title size, def label_text_size
volume_title_y_pos	mm	// if set, the height in mm above the // bottom of all the boxes that the // volume title text is drawn. // If not set, then the text is placed at a // height that puts it inside the default // box for the volumes.
volume_cut_title	text	// first line of volume sub title // default <i>cut</i>
volume_cut_title_textstyle	textstyle	// textstyle of the cut volume titles
volume_cut_title_colour	colour	// cut volume title colour, def box_colour
volume_cut_title_size	mm	// cut volume title size, def label_text_size
volume_cut_title_y	mm	// if set, the height in mm above the // default position. // If not set, then the text is placed at a // height that puts it inside the default // box for the cut volumes.
volume_fill_title	text	// first line of volume sub title // default <i>fill</i>
volume_fill_title_textstyle	textstyle	// textstyle of the fill volume titles
volume_fill_title_colour	colour	// fill volume title colour, def box_colour
volume_fill_title_size	mm	// fill volume title size, def label_text_size
volume_fill_title_y	mm	// if set, the height in mm above the // default position. // If not set, then the text is placed at a // height that puts it inside the default // box for the fill volumes.
volume_cut_textstyle	textstyle	// textstyle of the cut values
volume_cut_text_colour	colour	// cut value colour, def box_colour
volume_cut_text_size	mm	// cut value size, def label_text_size
volume_cut_text_x	mm	// the x distance to move the cut text from the // default cut text position, def 0, it is not used // if volume_text_centre_mode=1
volume_cut_text_y	mm	// the y distance to move the cut text from the // default cut text position, def 0
volume_cut_decimals	integer	// number decimal places in cut values //def number_of_decimals

volume_fill_textstyle	<i>textstyle</i>	// textstyle of the fill values
volume_fill_text_colour	<i>colour</i>	// fill value colour, def box_colour
volume_fill_text_size	<i>mm</i>	// fill value size, def label_text_size
volume_fill_text_x	<i>mm</i>	// the x distance to move the fill text from the // default fill text position, def 0, it is not used // if volume_text_centre_mode=1
volume_fill_text_y	<i>mm</i>	// the y distance to move the fill text from the // default fill text position, def 0
volume_fill_decimals	<i>integer</i>	// number decimal places in fill values //def number_of_decimals
volume_cl_linestyle	<i>linestyle</i>	// linestyle of horizontal cut/fill dividing line
volume_cl_line_colour	<i>colour</i>	// colour of horizontal cut/fill dividing line
volume_uprights_draw_mode	<i>0</i>	// default, don't draw cut/fill uprights
	<i>1</i>	// draw cut/fill uprights
volume_uprights_line_colour	<i>colour</i>	// colour of uprights
volume_sub_upright_colour	<i>colour</i>	// colour of sub uprights line
volume_sub_uprights_x	<i>mm</i>	// the distance to move from the default // sub uprights position, def 0
volume_sub_title_x	<i>mm</i>	// the distance to move the sub title text // from the volume sub uprights

Example of Volumes

           volume_sub_uprights_x            10

           volume_sub_title_x               3

```

X,Y Values

The values of the X and Y coordinate for selected chainages can be labelled as separate boxes. The chainages specified are limited to the base set of chainages already defined in the chainage selection and staggering section. i.e. an upright must exist for the X and Y value to be labelled. Not all of the uprights have to be labelled, just those specified in this section.

There are plot parameters to control all aspects of the X and Y labelling.

Chainages are used for positioning X and Y labels.

The chainages for the long section plot relate to the primary string and are controlled by a set of parameters.

xy_order	0		// 0 = X on bottom, Y on top
	1		// 1 = Y on bottom, X on top
xy_chord_arc	0		// don't use chord/arc chainages
	1		// include chainages for chord/arc
xy_start_chainage	<i>value</i>		// start chainage of labelling range
xy_end_chainage	<i>value</i>		// end chainage of labelling range
xy_interval	<i>value</i>		// regular interval (0 = no regulars)
xy_label_hcp	0/1		// 1 = include tangents, spirals
xy_label_hip	0/1		// 1 = include hip points
xy_label_vip	0/1		// 1 = include vip points
xy_label_vtp	0/1		// 1 = include tangent points
xy_label_crest	0/1		// 1 = include crest points
xy_label_sag	0/1		// 1 = include sag points
xy_label_grade_change	0/1		// 1 = include change of vertical grade
xy_special_n_file	<i>filename</i>		// n = 1 to 20 - include chainages from // the file (one chainage per line)
xy_label_tolerance	<i>value</i>		// > 0 use as weeding tolerance // <= 0, don't weed

For X parameters:

x_label	0/1		// 0 = Don't label X values/titles // 1 = Label X values/titles
x_title	<i>text</i>		// first line of X title // (default "Easting")
x_title_2	<i>text</i>		// second line of X title
x_title_textstyle	<i>textstyle</i>		// textstyle of the X titles
x_title_colour	<i>colour</i>		// default X title colour
x_title_size	<i>mm</i>		// default X title size
x_title_y_pos	<i>mm</i>		// if set, the height in mm above the // bottom of all the boxes that the // X title text is drawn. // If not set, then the text is placed at a // height that puts it inside the default // box for the X.
x_label_decimals	<i>integer</i>		// number of decim places for X values
x_label_textstyle	<i>textstyle</i>		// textstyle of the X values
x_label_colour	<i>colour</i>		// colour of X values, def is box_colour
x_label_size	<i>mm</i>		// size of X values, def is box_text_size
x_label_y_pos	<i>mm</i>		// if set, the height in mm above the // bottom of all the boxes that the // X value text is drawn. // If not set, then the text is placed at a // height that puts it inside the default // box for the X value.

For Y parameters:

y_label	0/1	// 0 = Don't label Y values/titles // 1 = Label Y values/titles
y_title	text	// first line of Y title // (default "Easting")
y_title_2	text	// second line of Y title
y_title_textstyle	textstyle	// textstyle of the Y titles
y_title_colour	colour	// default Y title colour
y_title_size	mm	// default Y title size
y_title_y_pos	mm	// if set, the height in mm above the // bottom of all the boxes that the // Y title text is drawn. // If not set, then the text is placed at a // height that puts it inside the default // box for the Y.
y_label_decimals	integer	// number of decim places for Y values
y_label_textstyle	textstyle	// textstyle of the Y values
y_label_colour	colour	// colour of Y values, def is box_colour
y_label_size	mm	// size of Y values, def is box_text_size
y_label_y_pos	mm	// if set, the height in mm above the // bottom of all the boxes that the // Y value text is drawn. // If not set, then the text is placed at a // height that puts it inside the default // box for the Y value.

Please continue to the next section "Chainage Selection and Staggering" .

Chainage Selection and Staggering

Chainages are used for positioning height labels, uprights (leader lines) and bubbles.

The chainages for the long section plot relate to the primary string and are controlled by a set of parameters.

chord_arc	0	// don't use chord/arc chainages
	1	// include chainages for chord/arc
chainage_interval	<i>value</i>	// regular interval (0 = no regulars)
chainage_label_ends	0/1	// 1 = include start and end chainages
chainage_label_hcp	0/1	// 1 = include tangents, spirals
chainage_label_hip	0/1	// 1 = include hip points
chainage_label_vip	0/1	// 1 = include vip points
chainage_label_vtp	0/1	// 1 = include tangent points
chainage_label_crest	0/1	// 1 = include crest points
chainage_label_sag	0/1	// 1 = include sag points
chainage_label_grade_change	0/1	// 1 = include change of vertical grade
chainage_special_n_file	<i>filename</i>	// n = 1 to 20 - include chainages from // the file (one chainage per line)
chainage_label_tolerance	<i>value</i>	// > 0 use as weeding tolerance // <= 0, don't weed
chainage_merge_bubbles	0/1	// 1 = merge in the bubble chainages
chainage_merge_tolerance	<i>value</i>	// > 0, weeding tol after bubble merge // <= 0, don't weed after merge

Default values

chainage_label_tolerance = 1.0 exp -4 (world units)

chainage_merge_tolerance = 1.0 exp -8 (world units)

If a tolerance is zero or negative, no weeding is performed.

The format of a chainage special file is simply a list of chainage values, one value per lines. Blank lines in the file are ignored and anything on a line after a // is a comment.

If the real chainage position is used for the horizontal position of the chainage/height/depth text, text over writing can easily occur.

To prevent over writing, the text can be **staggered**.

If the **stagger_mode** parameter is set to 1, the text position is adjusted so that the text does not over write.

The real chainage position is then indicated by the chainage markers which are drawn at the top of the text boxes from the staggered text position back to the actual chainage position of the text.

stagger_mode	0	// no staggering, allow over writing
	1	// stagger text to prevent over writing
stagger_gap_top	<i>mm</i>	// distance from boxes to top of stagger
stagger_gap_bottom	<i>mm</i>	// distance from boxes to bottom of // stagger
stagger_gap_factor	<i>value</i>	// distance between staggers is // box_text_size * stagger_gap_factor

When staggering occurs, it is possible for the heights area to be longer than the graph area.

Please continue to the next section “Uprights” .

Uprights

Uprights, or leader lines, can be drawn from the top of the staggers to the strings drawn on the plot.

The height of the uprights is given by the `uprights_draw_mode`:

<code>uprights_draw_mode</code>	0	// none
	1	// to maximum string height at that // chainage
	2	// ticks, to stagger height
	3	// to <code>uprights_y</code> above the boxes
	100	// to the primary string
	101-500	// to tin1 or tin2 etc.
	501-900	// to offset1 or offset2 etc.
<code>uprights_y</code>	<i>mm</i>	// distance to draw the uprights for // mode 3
<code>uprights_colour</code>	<i>colour</i>	// uprights colour (default <code>boxes_colour</code>)

The uprights can go below the top of the boxes.

<code>uprights_bottom_mode</code>	0	// stop at top of boxes (default)
	1	// draw to bottom of boxes
	2	// draw to <code>uprights_bottom_y</code> below the // top of the boxes
	3	// draw to <code>uprights_bottom_y</code> above the // bottom of the boxes
	4	// ticks at chainage
<code>uprights_bottom_y</code>	<i>mm</i>	//distance
<code>uprights_text_offset_factor</code>	<i>value</i>	// move the text by this factor*size

When uprights go below the top of the boxes, the height and offset text is moved to the left so that the upright does not go through the text. The left hand side of the heights boxes also moves to the left to leave room for the height text.

Please continue to the next section "Datum Area".

Datum Area

The **datum area** is the region between the boxes area and the graph area.

The **datum line** is positioned the distance *datum_below_gap* above the top of the boxes area and the graph area is positioned the distance *datum_above_gap* above the datum line.

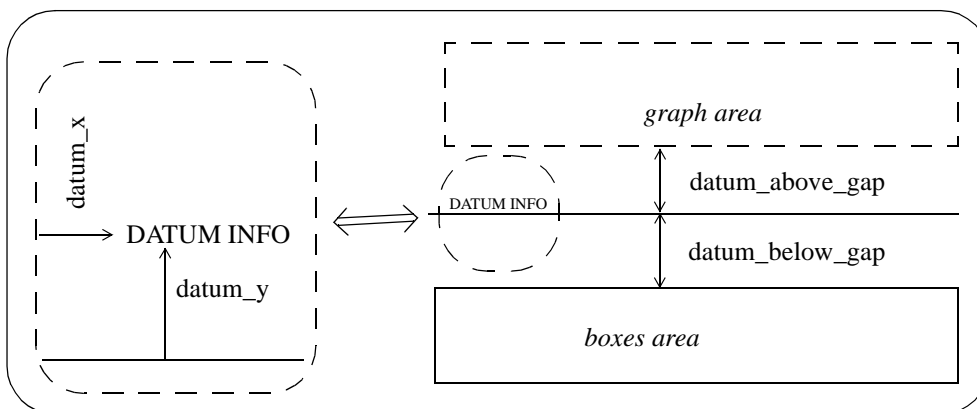

Hence the graph area is distance (*datum_below_gap* + *datum_above_gap*) above the top of the boxes area.

<i>datum_above_gap</i>	<i>mm</i>	// distance from datum line to the // bottom of the graph area
<i>datum_below_gap</i>	<i>mm</i>	// distance from datum line to the top of // the boxes
<i>datum_linestyle</i>	<i>linestyle</i>	// linestyle for datum line (default solid)

The *datum_below_gap* and *datum_above_gap* can be zero or positive.

A value for the datum can be specified by the parameter **datum_value** or if the *datum_value* is not set, a datum value is automatically calculated for the long section using a roundoff specified by the user (default 1.0).

<i>datum_value</i>	<i>value</i>	// if set, the value to use for datum. // If not set, the datum is automatically // calculated (using <i>datum_roundoff</i>)
<i>datum_roundoff</i>	<i>1.0</i>	// value to roundoff the datum value to // e.g. 0.5, 0.2, 1.0 (default 1.0)
<i>datum_decimals</i>	<i>integer</i>	// number of decimal places to display // the datum value (default 1). // If > 0, trailing zeros are removed after // the decimal point. // If < 0, the absolute value is taken as the // number of decimal places to report // i.e. no trailing zeros are removed
<i>datum_name</i>	<i>text</i>	// text to write before the datum value
<i>datum_textstyle</i>	<i>textstyle</i>	// textstyle for the datum text
<i>datum_text_size</i>	<i>mm</i>	// size of datum text and value
<i>datum_colour</i>	<i>colour</i>	// colour of the datum text and line
<i>datum_x</i>	<i>mm</i>	// distance to move the datum text // along the datum line
<i>datum_y</i>	<i>mm</i>	// distance to raise the datum text // above the datum line (used to be // called <i>datum_offset</i>)

Please continue to the next section “Graph Area” .

Graph Area

The **graph area** is the area where the actual plots of the strings are drawn.

The string used to define the horizontal position and chainage of the plot is called the **primary string** and is either

- (a) the string being profiled on the given section view
- or
- (b) the string given by the parameter

```
string_to_plot          "model->string_name"    // name of string to profile
```

When the primary string is being written out to a plot parameter file by **12d Model**, a *string_to_plot* parameter and special parameters recording the internal id's for the string and it's model are all written out.

```
primary_model_id      integer                // internal 12d Model parameter
primary_string_id     integer                // internal 12d Model parameter
```

The **length** of the graph area is determined by the length of the primary string being plotted (restricted to the specified start and end chainages) and the horizontal scale (scale) given by parameters or in the **section long plot** panel, and the vertical exaggeration given by the section view or a parameter.

```
view_name             text                   // default is section view in panel.
vertical_exaggeration value                 // default is vertical exag for the view
scale                 value                 // 1:value - horizontal scale, default is
// scale 1: in panel
start_chainage        value                 // "" means use start of primary string
end_chainage          value                 // "" means use end of primary string
```

The vertical scale is determined by the horizontal scale and the vertical exaggeration.

The **height** of the graph area is determined by the vertical scale (given by the horizontal scale and the vertical exaggeration) and the minimum and maximum values of the data being plotted. Hence the graph height is a calculated rather than a given value.

The types of strings that can be drawn in the graph area of a long section plot are:

- (a) primary string the string being profiled (usually the design string).
- (b) tins sections of the primary string through any tins either in models on the section view or in corridor models.
- (c) offset strings strings in the **offset model** that are projected back onto the primary string
- (d) services parts of strings (from either models on the section view or in corridor models) that cut the defined corridor.

The **colour** of the strings in the plot is the actual string colour for cases (a), (c) and (d), and the colour of the tin used for the section in case (b).

Although all the strings are plotted, the plot parameter file can be used to select which ones are labelled with heights and/or depths.

Primary String (Design String)

The primary string (the design string) is used to define

- (a) the design long section
- (b) the chainage positions for labelling heights and drawing uprights
- (c) the section line used for sectioning through tins
- (d) the section line for defining the corridor for services

Although the primary string is used to set up most of the information for the long section plot, it doesn't have to be drawn on the long section.

The drawing or not drawing of the primary string on each cross section plot is controlled by the parameter *primary_string* which was described earlier.

The **colour** of the primary string in the plot is the actual primary string colour.

Tins

A section along the primary string through each tin on the specified section view is automatically drawn on the cross section plot.

The **colour** and **linestyle** of the tin section in the plot is the actual tin colour and tin linestyle.

Whether the tin heights are labelled or not in the boxes area is controlled by parameters and has been described earlier

Corridor and Services

A corridor around the primary string is defined by giving a left and right corridor width.

Any string in a model added to the section view is checked to see if it appears in the corridor, and if it does, then it is drawn on the long section plot.

To be drawn, strings do not have to cross the primary string, but just be in the corridor.

The corridor defining parameters are

<code>corridor_width_left</code>	<code>world-units</code>	// corridor left and right widths
<code>corridor_width_right</code>	<code>world-units</code>	// defaults are the section view values
<code>corridor_overlap_left</code>	<code>world-units</code>	// corridor left and right overlaps.
<code>corridor_overlap_right</code>	<code>world-units</code>	// defaults are the section view values
<code>corridor_chord_arc</code>	<code>world-units</code>	// chord-arc tolerance used to // approximate arcs in the corridor. // default is the section view value

The models containing tins for sectioning and strings for services are taken from the section view or given by the parameters

<code>corridor_model_n</code>	<code>model</code>	// n = 1, 2 ... 100 // models containing tins and service // strings to be drawn on the view.
-------------------------------	--------------------	---

If any *corridor_model_n* parameters are defined, then only the models given by the parameters are used. If no *corridor_model_n* parameters are set, then the models added to the given section view

are used.

That is, either the *corridor_model_n* parameters are used or if none exist, then the models added to the section view are used for tins and service strings.

The **colour** and **diameter** of the service strings drawn in the plot are the actual strings colour and diameter.

The graph area sits on top of the boxes and datum areas, so there may not be enough room left on the sheet for the full plot height. In this case, the plot will be truncated at the top of the allowed graph area.

Please continue to the next section “Bubbles Definitions” .

Bubbles Definitions

Circles with the string name and a unique number (**bubbles**) can be drawn on the long section plot. Bubbles are normally used for lip profiles.

The chainages used for the bubbles are given by a set of parameters similar to the chainage parameters. The resulting set of bubbles are sequentially numbered (starting with one) in chainage order.

Although many bubbles can be defined by the bubble parameters, a bubble is only drawn on the plot if there is a labelled chainage to draw it above.

Hence not all bubbles given by the bubble chainage parameters are drawn but for the ones that are drawn, the bubble number is taken from the full bubble set.

chainage_bubbles	0	// don't drawn bubbles
	1	// draw bubbles
bubble_radius	<i>mm</i>	// radius of the bubbles
bubble_colour	<i>colour</i>	// colour for the bubbles
bubble_text_string_name_mode0		// do not label with string name
	1	// label string name
	2	// label with model->string name
bubble_pre_text	<i>text</i>	
bubble_post_text	<i>text</i>	
bubble_textstyle	<i>textstyle</i>	
bubble_text_size	<i>mm</i>	
bubble_text_colour	<i>colour</i>	
bubble_text_offset	<i>mm</i>	
bubble_upright_distance	<i>mm</i>	// distance bubbles are above boxes/uprights
bubble_mode	0	// bubble_upright_distance is above boxes
	1	// bubble_upright_distance is above
		// uprights
bubble_draw_upright	0/1	// 1 = draw extra upright if
		// bubble_mode = 1
bubble_start_chainage	<i>value</i>	// start chainage for bubbles
bubble_end_chainage	<i>value</i>	// end chainage for bubbles
bubble_chord_arc	0/1	// 1 = use chord-arc chainages
bubble_interval	<i>value</i>	// include regular interval
		// (0 = no regulars)
bubble_label_ends	0/1	// 1 = include start and end chainages
bubble_label_hcp	0/1	// 1 = include tangents, spirals
bubble_label_hip	0/1	// 1 = include hip points
bubble_label_vip	0/1	// 1 = include vip points
bubble_label_vtp	0/1	// 1 = include tangent points
bubble_label_crest	0/1	// 1 = include crests
bubble_label_sag	0/1	// 1 = include sags
bubble_label_grade_change	0/1	// 1 = include change of grade
bubble_special_n_file	<i>filename</i>	// n = 1 to 20 include chainages from the
		// file
bubble_label_tolerance	<i>value</i>	// > 0 use as weeding tolerance
		// <= 0, don't weed

Defaults

bubble_label_tolerance = 1.0 exp -4 (world units)

If a tolerance is zero or negative, no weeding is performed.

The format of a bubble special file is simply a list of chainage values, one value per lines. Blank lines in the file are ignored and anything on a line after a // is a comment.

Please continue to the next section “Quick Horizontal Geometry Labelling” .

Quick Horizontal Geometry Labelling

The standard horizontal geometry arrows can be drawn at a given distance above the top of the boxes area.

```

horizontal_geometry_y'                mm                // dist above boxes
                                           // 0 = don't draw

horizontal_geometry_arrow_text_colour  colour
horizontal_geometry_arrow_textstyle   textstyle
horizontal_geometry_arrow_text_size   mm
horizontal_geometry_arrow_colour      colour
horizontal_geometry_arrow_height      mm
horizontal_geometry_label_text        text
horizontal_geometry_label_textstyle   textstyle
horizontal_geometry_label_text_colour  colour
horizontal_geometry_label_text_size   mm
horizontal_geometry_label_decimals    number

```

Please continue to the next section “Extensive Horizontal Geometry Labelling” .

Extensive Horizontal Geometry Labelling

For complicated horizontal geometry labelling, there are sets of horizontal geometry labelling parameters which give tight control over the position and types of labels.

It is also possible to label the horizontal geometry of **alignment** strings other than the primary string. To plot such a string on the same plot, the chainage position of the horizontal geometry for the non-primary alignment strings is *projected* onto the primary string to give a primary string chainage for plotting. The values of the horizontal geometry (such as radius and spiral length) that are plotted are taken from the other string. Independently graded offset strings (such as a left and right kerbs) are the type of additional alignment strings that may need to be plotted on the same long section plot as the reference string (primary string).

For plotting horizontal geometry, the user can give up to twenty sets of these labels and they can be used to label spirals, curves and tangent information for the primary string and/or additional alignment strings.

Each label set consists of three parts:

- (a) a text label on the left hand side of the plot
- (b) an arrow
- (c) text on the arrows.

For the following parameters, n takes the value 1 to 20 and specifies the nth parameter set.

```

h_g_n_type          0                // label spirals
                    1                // label horizontal curves
                    2                // label horizontal tangents

```

If *h_g_n_type* is missing, then the set is ignored.

```

h_g_n_value_mode
for spiral labelling  0                // nothing
                    1                // length
for curve labelling  0                // nothing
                    1                // length
                    2                // radius
for tangent labelling 0                // nothing

```

```

for spiral labelling      1 // length
                        0 // nothing
                        1 // length
                        2 // radius*length
      h_g_n_label_y      mm // distance of arrow line above the top of
                        // the boxes

```

Parameters for the left hand label of the line of the horizontal geometry arrows:

```

      h_g_n_label_x      mm // distance from the left hand side of the
                        // labels area
      h_g_n_label_offset mm // distance to raise the label_text above
                        // arrow line

      h_g_n_label_text_size mm
      h_g_n_label_text_colour colour
      h_g_n_label_text text
      h_g_n_label_textstyle textstyle // textstyle used

```

Parameters for arrow type

```

      h_g_n_draw_mode    0 // no arrow
                        1 // arrow
                        2 // line
                        3 // line with uprights at ends
                        4 // uprights, no line
                        5 // line with downrights
                        6 // downrights, no line
                        7 // line with up and downrights at ends
                        8 // up and downrights, no line
                        9 // draw curve
                       11 // radius*length curve

```

```

      h_g_n_left_gap     mm // size of gap for left side of arrow
      h_g_n_right_gap    mm // size of gap for right side of arrow
      h_g_n_colour       colour // colour of the arrow
      h_g_n_height       mm // height of the arrow
      h_g_n_gap          0 // no gap
                        1 // leave gap in arrow for text

```

Parameters for text on the arrows

```

      h_g_n_text_colour  colour // colour of the text
      h_g_n_text_size    mm // size of the text
      h_g_n_text_offset mm // distance to raise the text above the
                        // arrow line

      h_g_n_pre_text     text // text before the arrow text
      h_g_n_post_text    text // text after the arrow text
      h_g_n_textstyle    textstyle // textstyle used

```

```

h_g_n_no_decimals      integer      // number of decimal places in arrow
                        // text.
                        // If > 0, all trailing zeros after the
                        // decimal place are removed.
                        // If < 0, the absolute value is taken as
                        // the number of decimal places and no
                        // trailing zeros are removed after the
                        // decimal point.
h_g_n_rotate           mm              // if ticked, the text on the arrows will be
                                        rotated to fit.

```

If the set of parameters is to apply to the horizontal geometry of an alignment string *other* than the primary string, then simply add the following parameter to define the other alignment string

```

h_g_n_offset_string    "model->string_name"
or
h_g_n_offset_string    "string_name"

```

and the model is the *Offsets model* from the **Section Long Plot** panel.

If the *h_g_n_offset_string* parameter does not exist, then the set of horizontal geometry parameters is applied to the primary string.

Example of Extensive Horizontal Geometry

```

// Parameter to stop the drawing of the quick horizontal geometry
horizontal_geometry_y  0
// Set 1 - Extensive Horizontal Geometry Labelling - label the horizontal curve radius
h_g_1_type             1              // label horizontal curve
                        // if this param is missing then set is ignored
h_g_1_value_mode       2              // label curve radius
h_g_1_label_y          45
h_g_1_label_x          0
h_g_1_label_offset     2
h_g_1_label_text_size  4
h_g_1_label_text_colour YELLOW
h_g_1_label_text       "Horiz Curve Data"
// Parameters for arrow type
h_g_1_draw_mode        1
h_g_1_colour           "white"
h_g_1_height           1.5
h_g_1_gap              0
// Parameters for text on the arrows
h_g_1_text_colour      YELLOW
h_g_1_text_size        3.5
h_g_1_text_offset      2.5
h_g_1_pre_text         "R"
h_g_1_post_text        "m"
h_g_1_no_decimals     2

```

Example of Extensive Horizontal Geometry for use with a Non-primary Alignment String

```
// Set 2 labels the horizontal curves radii of the kerb string projected onto primary stings
h_g_2_offset_string      "left offsets->kerb"      // non-primary string to do VG of
h_g_2_type              1                        // label horizontal curve
                                                // if this param is missing then set is ignored
h_g_2_value_mode        2                        // label curve radius
h_g_2_label_y           55
h_g_2_label_x           0
h_g_2_label_offset      2
h_g_2_label_text_size   4
h_g_2_label_text_colour GREEN
h_g_2_label_text        "Left Kerb - Horiz Curve Data"

// Parameters for arrow type
h_g_2_draw_mode         1
h_g_2_colour            "white"
h_g_2_height            1.5
h_g_2_gap               0

// Parameters for text on the arrows
h_g_2_text_colour       GREEN
h_g_2_text_size         3.5
h_g_2_text_offset       2.5
h_g_2_pre_text          "R"
h_g_2_post_text         "m"
h_g_2_no_decimals       2
```

Please continue to the next section “Quick Vertical Geometry Labelling” .

Quick Vertical Geometry Labelling

The standard vertical geometry arrows can be drawn at a given distance above the top of the boxes area.

vertical_geometry_grade_y	<i>mm</i>	// dist above boxes // 0 = don't draw
vertical_geometry_grade_mode	0 1	// % // 1 in
vertical_geometry_label_grade_text	<i>text</i>	
vertical_geometry_label_grade_textstyle	<i>textstyle</i>	// textstyle to use
vertical_geometry_label_grade_text_colour	<i>colour</i>	
vertical_geometry_label_grade_text_size	<i>mm</i>	
vertical_geometry_label_grade_decimals	<i>number</i>	
vertical_geometry_length_y	<i>mm</i>	// dist above boxes // 0 = don't draw

Please continue to the next section "Extensive Vertical Geometry Labelling".

Extensive Vertical Geometry Labelling

For complicated vertical geometry labelling of the *primary alignment* string, there are sets of vertical geometry labelling parameters which give tight control over the position and types of labels.

It is also possible to label the vertical geometry of **alignment** strings other than the primary string. To plot such a string on the same plot, the chainage position of the vertical geometry for the non-primary alignment strings is *projected* onto the primary string to give a primary string chainage for plotting. The values of the vertical geometry (such as grade and curve length) that are plotted are taken from the other string. Independently graded offset strings (such as a left and right kerbs) are the type of additional alignment strings that may need to be plotted on the same long section plot as the reference string (primary string).

For plotting vertical geometry, the user can give up to twenty sets of these labels and they can be used to label grades or vertical curve information for the primary string and/or additional alignment strings.

Each label set consists of three parts:

- (a) a text label on the left hand side of the plot
- (b) an arrow
- (c) text on the arrows.

For the following parameters, *n* takes the value 1 to 20 and specifies the *n*th parameter set.

<i>v_g_n_type</i>	0	// labelling grades
	1	// labelling vg curve information

If *v_g_n_type* is missing, then the entire *n*th set is ignored.

The interpretation of the value of the

parameter *v_g_n_value_mode* depends on whether the set is being used for grade labelling or curve labelling:

<i>v_g_n_value_mode</i>		
for grade labelling	0	// nothing
	1	// % grade
	2	// 1 in grade
	3	// m/m grade
	4	// chainage length between vertical // curve points
	5	// per chord - Queensland Rail
for curve labelling	0	// nothing
	1	// length - chainage for parabolic vc's // arc length for circular vc's
	2	// radius
	3	// K value
	5	// curve constant - Queensland Rail

Vertical curve points to draw the arrows between (for grade labelling only)

<i>v_g_n_between_mode</i>	0	// between chainages at the vip's
	1	// between chainages at the vtp's

Position of the Arrow Line

<i>v_g_n_label_y</i>	<i>mm</i>	// distance of arrow line above the top of // the boxes this can be negative
----------------------	-----------	---

Parameters for the left hand label of the whole line of the vg arrows:

<i>v_g_n_label_x</i>	<i>mm</i>	// distance from the left hand side of the // labels area
<i>v_g_n_label_offset</i>	<i>mm</i>	// distance to raise the label_text above // arrow line
<i>v_g_n_label_text</i>	<i>text</i>	
<i>v_g_n_label_textstyle</i>	<i>textstyle</i>	
<i>v_g_n_label_text_size</i>	<i>mm</i>	
<i>v_g_n_label_text_colour</i>	<i>colour</i>	

Parameters for arrow type

<i>v_g_n_draw_mode</i>	0	// no arrow
	1	// arrow
	2	// line
	3	// line with uprights at ends
	4	// uprights, no line
	5	// line with downrights
	6	// downrights, no line

```

7 // line with up and downrights at ends
8 // up and down rights, no line
9 // draw curve
10 // draw grade

```

```

v_g_n_left_gap      mm // size of gap for left side of arrow
v_g_n_right_gap     mm // size of gap for right side of arrow
v_g_n_colour        colour // colour of the arrow
v_g_n_height        mm // height of the arrow
v_g_n_gap           0 // no gap
                   1 // leave gap in arrow for text

```

Parameters for text on the arrows

```

v_g_n_text_colour   colour // colour of the text
v_g_n_text_size     mm // size of the text
v_g_n_text_offset   mm // distance to raise the text above the
                       // arrow line

v_g_n_pre_text      text // text before the arrow text
v_g_n_post_text     text // text after the arrow text
v_g_n_textstyle     textstyle // textstyle used
v_g_n_no_decimals   integer // number of decimal places in arrow
                           // text.
                           // If > 0, all trailing zeros after the
                           // decimal place are removed.
                           // If < 0, the absolute value is taken as
                           // the number of decimal places and no
                           // trailing zeros are removed after the
                           // decimal point.

v_g_n_rotate        mm // if ticked, the text on the arrows will be
                       // rotated to fit.

```

If the set of parameters is to apply to the vertical geometry of an alignment string *other* than the primary string, then simply add the following parameter to define the other alignment string

```

v_g_n_offset_string "model->string_name"
or
v_g_n_offset_string "string_name"

```

and the model is the *Offsets model* from the **Section Long Plot** panel.

If the *v_g_n_offset_string* parameter does not exist, then the set of vertical geometry parameters is applied to the primary string.

Example of Extensive Vertical Geometry

```
// Parameter to not to draw the quick vertical geometry
vertical_geometry_grade_y    0

// Set 1 labels the vertical curves with length
v_g_1_type                  1 // curve
v_g_1_value_mode            1 // chainage length

v_g_1_label_y               45
v_g_1_height                 4
v_g_1_label_offset          -2
v_g_1_label_text             "VG Curves"
v_g_1_text_offset            2
v_g_1_label_text_size        6
v_g_1_pre_text               ""
v_g_1_post_text              "L"
v_g_1_gap                    0
v_g_1_draw_mode              8
v_g_1_text_size              4

// Set 2 labels the vertical curves with K value
v_g_2_type                  1 // curve
v_g_2_value_mode            3 // K value

v_g_2_label_y               45
v_g_2_height                 1.5
v_g_2_label_text             ""
v_g_2_text_offset            -5
v_g_2_pre_text               ""
v_g_2_post_text              "K"
v_g_2_gap                    0
v_g_2_draw_mode              1
v_g_2_text_size              4
```

Example of Extensive Vertical Geometry for use with a Non-primary Alignment String

```
// Set 3 labels the vertical curves with length with the kerb string projected onto primary strings
v_g_3_offset_string         "left offsets->kerb" // non-primary string to do VG of
v_g_3_type                  1 // curve
v_g_3_value_mode            1 // chainage length

v_g_3_label_y               55
v_g_3_height                 4
v_g_3_label_offset          -2
v_g_3_label_text             "Left kerb - VG Curves"
v_g_3_text_offset            2
v_g_3_label_text_size        6
v_g_3_pre_text               ""
v_g_3_post_text              "L"
v_g_3_gap                    0
v_g_3_draw_mode              8
v_g_3_text_size              4
```

Please continue to the next section “Labelling Chainages and Heights in the Graph Area” .

Labelling Chainages and Heights in the Graph Area

The chainage and/or height values for certain points (given by *label_n_type*) can be labelled.

Up to twenty sets of chainage/height labels can be done.

<i>label_n_type</i>	0	// chainage of vip, height of vip
	1	// chainage of vip, height of primary
	2	// crest
	3	// sag
	4	// vtp
	5	// hcp
	6	// change of grade
	7	// mid-ordinate of the vertical curve

If *label_n_type* is missing, then the set is ignored.

<i>label_n_y_mode</i>	0	// height in mm above boxes
	1	// above height value (default)
	2	// above primary height
<i>label_n_y</i>	<i>mm</i>	// distance above point
<i>label_n_angle</i>	<i>degrees</i>	// rotation about point
<i>label_n_x</i>	<i>mm</i>	// distance along from point
<i>label_n_offset</i>	<i>mm</i>	// text raise height
<i>label_n_justification</i>	0	// left end
	1	// middle
	2	// end
<i>label_n_size</i>	<i>mm</i>	
<i>label_n_colour</i>	<i>size</i>	
<i>label_n_textstyle</i>	<i>textstyle</i>	
<i>label_n_value_mode</i>	0	// no values labelled
	1	// val 1 = chainage
	2	// val 1 = height
	3	// val 1 = chainage, val 2 = height
	4	// val 1 = height, val 2 = chainage
<i>label_n_pre_text</i>	<i>text</i>	
<i>label_n_mid_text</i>	<i>text</i>	
<i>label_n_post_text</i>	<i>text</i>	
<i>label_n_textstyle</i>	<i>textstyle</i>	// <i>textstyle</i> to use
<i>label_n_no_decimals_1</i>	<i>integer</i>	// number of decimal places in val 1
<i>label_n_no_decimals_2</i>	<i>integer</i>	// number of decimal places in val 2

If the **number of decimal places is greater than zero (> 0)**, then any trailing zeros after the decimal point are removed.

If the **number of decimal places is less than zero (< 0)**, the absolute value is taken as the number of decimal places and **no** trailing zeros after the decimal point are removed.

Example of Labelling Chainage and Heights

```
// label the crests with chainage on one line
// and height (elevation) on the next

label_1_type      2 // crest
label_1_y_mode    2 // above string
label_1_y         10
label_1_angle     0
label_1_justification 1 // centre
label_1_size      4
label_1_colour    red
label_1_value_mode 1 // chainage
```

```

label_1_pre_text      "CH "
label_1_no_decimals_1 1
label_2_type          2 // crest
label_2_y_mode        2 // above string
label_2_y              2
label_2_angle          0
label_2_justification 1 // centre
label_2_size           4
label_2_colour         red
label_2_value_mode     2 // height
label_2_pre_text      "EL "
label_2_no_decimals_1 1

```

Please continue to the next section "Labelling With Symbols" .

Labelling With Symbols

Symbols can be placed at certain points given by *symbol_n_type*.

The symbol is drawn in a square box centred on (0,0) with sides of length two millimetres. That is, the box co-ordinates are (-1,-1), (1,1), (1,-1), (-1,-1).

Up to twenty sets of symbol labelling can be done.

```

symbol_n_type          0 // chainage of vip, height of vip
                      1 // chainage of vip, height of primary
                      2 // crest
                      3 // sag
                      4 // vtp
                      5 // hcp
                      6 // change of grade

```

If *symbol_n_type* is missing, then the set is ignored.

```

symbol_n_y_mode        0 // height in mm above boxes
                      1 //   above height value (default)
                      2 //   above primary height

symbol_n_y              mm // distance above point given by mode
symbol_n_angle          degrees // rotation about point
symbol_n_x              mm // distance along from point
symbol_n_size           mm //
symbol_n_colour         colour // colour of symbol

symbol_n_draw_mode     0 // cross
                      1 // upright from centre of box
                      2 // up and downright from centre of box
                      3 // square
                      4 // triangle, base at bottom
                      5 // circle

```

Example of Labelling with Symbols

```

// draw a triangle symbol at the crest
symbol_1_type          2 // crest

```

```

symbol_1_y_mode      2 // above string
symbol_1_y           0
symbol_1_angle       0
symbol_1_size        2
symbol_1_colour      red
symbol_1_draw_mode   4 // triangle
    
```

Please continue to the next section “Hatching Cut and Fill Areas” .

Hatching Cut and Fill Areas

This option is used to hatch cut and/or fill areas between sets of tins.

For each set, the name of the two tins, the hatch linestyle, colour and separation and whether cut and/or fill regions are required are all user definable.

Up to twenty (20) separate sets of tins be hatched.

The parameters for labelling cuts and/or fill regions between tins are given by:

<code>hatch_original_tin_n</code>	<code>tin_name</code>	// tin_name for original surface
<code>hatch_new_tin_n</code>	<code>tin_name</code>	// tin_name for final surface
<code>hatch_cut_separation_n</code>	<code>mm</code>	// distance between cut hatch lines
	<code>0</code>	// don't do cut hatching
<code>hatch_cut_angle_n</code>	<code>degrees</code>	// angle in degrees of cut hatching
<code>hatch_cut_colour_n</code>	<code>colour</code>	// colour of the cut hatching
<code>hatch_cut_linestyle_n</code>	<code>linestyle</code>	// linestyle for cut hatching
<code>hatch_cut_draw_sides_n</code>	<code>1/0</code>	// 1 = draw sides of cut regions
<code>hatch_cut_draw_original_n</code>	<code>1/0</code>	// 1 = draw original tin in cut regions
<code>hatch_cut_draw_new_n</code>	<code>1/0</code>	// 1 = draw new tin in cut regions
<code>hatch_fill_separation_n</code>	<code>mm</code>	// distance between fill hatch line
	<code>0</code>	// don't do fill hatching
<code>hatch_fill_angle_n</code>	<code>degrees</code>	// angle in degrees of fill hatching
<code>hatch_fill_colour_n</code>	<code>colour</code>	// colour of the fill hatching
<code>hatch_fill_linestyle_n</code>	<code>linestyle</code>	// linestyle for fill hatching
<code>hatch_fill_draw_sides_n</code>	<code>1/0</code>	// 1 = draw sides of fill regions
<code>hatch_fill_draw_original_n</code>	<code>1/0</code>	// 1 = draw original tin in fill regions
<code>hatch_fill_draw_new_n</code>	<code>1/0</code>	// 1 = draw new tin in fill regions

Notes

- (a) cut is when the new tin is below the original tin.
fill is when the new tin is above the original tin.
- (b) cut hatching is turned off by setting `hatch_cut_separation_n` to 0.0.
fill hatching is turned off by setting `hatch_fill_separation_n` to 0.0.

Please continue to the next section “Labelling Cuts of Design Through Strings in a Model” .

Labelling Cuts of Design Through Strings in a Model

The cuts that the primary string (design line) makes through any strings in user given models can be automatically labelled on the long section plots.

The **height**, **chainage** and **name** of the cut string can be labelled as well as a **symbol**. The height of tins at the same offset value can also be labelled.

The chainage position for the labelling is the chainage of the cut string.

The height position for the labelling can be specified as the

- (a) top of the boxes on the long section
- (b) height value of the cut string
- (c) height of the primary string
- (d) height of a tin.

The actual position of the label is defined relative to the above point.

Note:

Only case (b) involves the actual height of the cut string. For all other cases, only the chainage of the cut string is used. Hence for all cases except (b), the string does need to have a sensible height to be used for cuts through strings.

For example, a boundary string may have null heights but only the chainage is required and the height of the tin at that chainage can be used as the height (case (d)).

Text justification refers to the actual position and is given by

“top-left”	“top-centre”	“top-right”
“middle-left”	“middle-centre”	“middle-right”
“bottom-left”	“bottom-centre”	“bottom-right”

A choice of six special symbols and/or any 12d symbols can be drawn at the cut point.

The special 12d Model symbols of size one millimetre are drawn in a square box centred on (0,0) with sides of length two millimetres. That is, the box co-ordinates are (-1,-1), (1,1), (1,-1), (-1,-1).

The six special shapes are

Up to twenty five (25) separate models of strings can be cut and labelled.

Parameters for Labelling Where the Design Cuts Strings in a Model

The method for specifying which strings are to be checked for cuts is by first specifying the **model** which contains the strings, and then a **name mask** which is used to restrict the strings in the model to only those whose name matches the name mask.

Up to twenty five different sets of models and name masks can be used so that different cut sets can be labelled in different ways.

The parameters for selecting and labelling the *n*th set (where *n* can be from 1 to 25) of cuts of the design string with the strings in the model are given by:

```
cuts_n_model          model_name          // model of strings to be cut
```

The selection of the strings from the model *model_name* whose cut points are to be labelled is all the strings whose name satisfies the name mask *cuts_n_mask*:

```
cuts_n_mask          name_mask          // strings to check for cuts
                                     // and if a cut occurs,
                                     // parameters show how to
                                     // label the cut
```

where *name_mask* is a text string containing the name masks, each separated by one or more spaces, to test the string name against. Each mask can include wild cards and wild characters.

For example

```
or          cuts_1_mask          "ke*"
           cuts_1_mask          "?bank*"
```

or, if both masks are required,

```
           cuts_1_mask          "ke* ?bank*"
```

If *cuts_n_mask* is missing, then all strings in the model are used. This is equivalent to *name_mask* being "*".

All strings in the model *cuts_n_model* whose name satisfy the name mask *cuts_n_mask* are then checked for cuts with the design string, and if a cut occurs, the cut point will be labelled according to the rest of the parameters in the *n*th set.

The parameters for drawing a **symbol** at the cut points are

```
cuts_symbol_n_mode    0          // cross
                     1          // up from centre of box
                     2          // up and down from centre of box
                     3          // square
                     4          // triangle, base at bottom
                     5          // circle
                     6          // use a 12d symbol
```

0 + 1 | 2 | 3 □ 4 △ 5 ○

predefined symbols for

If *cuts_symbol_n_mode* is 6, then the 12d symbol is given by

```
cuts_symbol_n_style    plotsymbol    // plot symbol to draw at cut
```

Important Note

The plot symbol of name *plotsymbol* is defined in the file given by:

- (a) the parameter *plot_symbols* in the ppf file

plot_symbols filename

or if plot_symbols is not defined, then

(b) in the file pointed to by the environment variable PLOT_SYMBOLS_4D
PLOT_SYMBOLS_4D filename // default plotsym.4d

or if PLOT_SYMBOLS_4D is not defined, then

(c) in the file *plotsym.4d*
which is searched for in the standard set up file sequence

If none of the above files are defined, or if the symbol does not exist in the above files, then it will be searched for in the standard 12d symbols file which is:

(d) either pointed to by the environment variable SYMBOLS_4D
SYMBOLS_4D filename // default symbols.4d
or if the environment variable SYMBOLS_4D does not exist, in the file, *symbols.4d*

The position of the symbol is given by:

cuts_symbol_n_position	1	// above point height value
	3	// above top of boxes
	100	// to primary string
	101-500	// to tin1 or tin2 etc.

The symbol can be adjusted by the parameters:

cuts_symbol_n_x	mm	// offset adjustment to position
cuts_symbol_n_y	mm	// height adjustment to position
cuts_symbol_n_angle	degrees	// rotation about point
cuts_symbol_n_colour	colour	// colour of symbol

and for all values of *cuts_symbol_n_mode* **other** than 6:

cuts_symbol_n_size	mm	// size of symbol, 0 don't draw
--------------------	----	---------------------------------

The value of the **chainage** of the cut string can be labelled using the parameters

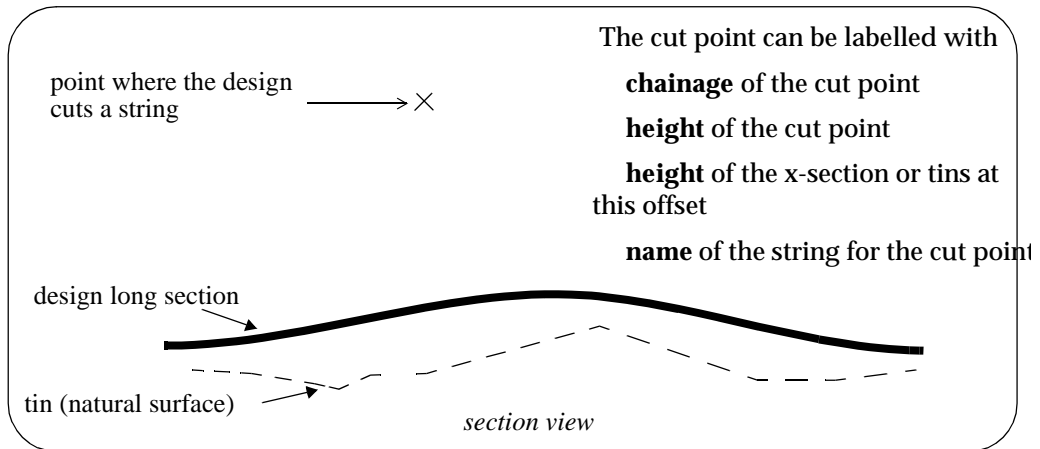

cuts_chainage_n_position	1	// above cut strings height value
	3	// above top of boxes
	100	// to primary string
	101-500	// to tin1 or tin2 etc.
cuts_chainage_n_x	mm	// chainage adjustment to position
cuts_chainage_n_y	mm	// height adjustment to position
cuts_chainage_n_angle	degrees	// rotation about point
cuts_chainage_n_size	mm	// size of text, 0 don't label
cuts_chainage_n_colour	colour	// colour of text
cuts_chainage_n_textstyle	text	// textstyle of text chainage
cuts_chainage_n_pre_text	text	// text before the chainage value
cuts_chainage_n_post_text	text	// text after the chainage value
cuts_chainage_n_justification	justification	// justification of the text
cuts_chainage_n_no_decimals	integer	// number of decimals in chainage

The value of a **height** at the chainage of the point can be calculated and labelled using the parameters

cuts_height_n_mode	1	// use height of cut point itself
	3	// use real world height of the position // of the label above the boxes
	100	// height of primary string
	101-500	// use height of to tin1 or tin2 etc.
cuts_height_n_position	1	// at points position
	3	// above top of boxes
	100	// to primary string
	101-500	// to tin1 or tin2 etc.
cuts_height_n_x	mm	// chainage adjustment to position
cuts_height_n_y	mm	// height adjustment to position
cuts_height_n_angle	degrees	// rotation about point
cuts_height_n_size	mm	// size of text, 0 don't label
cuts_height_n_colour	colour	// colour of text
cuts_height_n_textstyle	text	// textstyle of text height
cuts_height_n_pre_text	text	// text before the height value
cuts_height_n_post_text	text	// text after the height value
cuts_height_n_justification	justification	// justification of the text
cuts_height_n_no_decimals	integer	// number of decimals in height

A **label** which can include the **name** of the cut string is drawn by using the parameters

cuts_label_n_position	1	// above cut strings height value
	3	// above top of boxes
	100	// to primary string
	101-500	// to tin1 or tin2 etc.
cuts_label_n_mode	0	// don't include cut string name
	1	// include cut string name in label
cuts_label_n_x	mm	// chainage adjustment to position
cuts_label_n_y	mm	// height adjustment to position
cuts_label_n_angle	degrees	// rotation about point
cuts_label_n_size	mm	// size of text, 0 don't label
cuts_label_n_colour	colour	// colour of text
cuts_label_n_textstyle	text	// textstyle of text label
cuts_label_n_pre_text	text	// text before the string name
cuts_label_n_post_text	text	// text after the string name
cuts_label_n_justification	justification	// justification of the text

Please continue to the next section “Labelling the Primary String Name on the Plot” .

Labelling the Primary String Name on the Plot

The plot can be labelled with a name under the boxes area.

The name is made up of concatenation the text strings:

```
plot_name_pre_text      primary-string-name      plot_name_post_text
```

The plot name is positioned under the boxes.

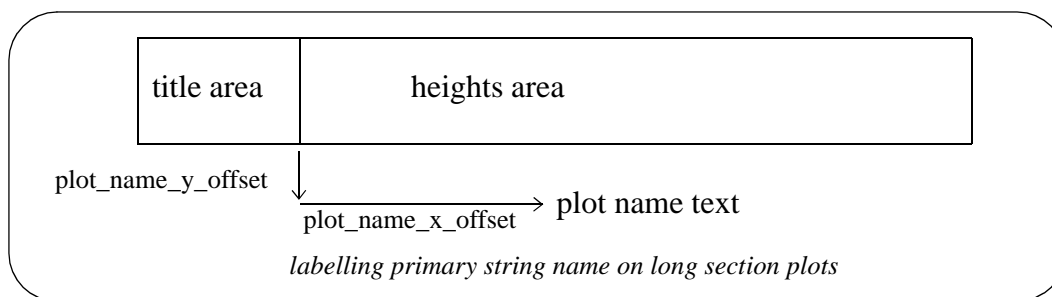

```
plot_name_string_name      0          // don't use the primary string name
                           1          // use primary string name
                           2          // use model->string name

plot_name_pre_text        text
plot_name_post_text       text
plot_name_textstyle       textstyle
plot_name_size            mm
plot_name_colour          colour
plot_name_x_offset        mm
plot_name_y_offset        mm
```

The *plot_name_x_offset* is measured from the beginning of the height boxes.

The default for *plot_name_x_offset* is centred on heights area.

The *plot_name_y_offset* is measured from the bottom of the box area with positive being **down**.

Example of Labelling Primary String Name

```
plot_name_pre_text      "Long Section Plot for String"
plot_name_post_text     ""
plot_name_size          15
plot_name_colour        red
plot_name_string_name   1
plot_name_y_offset      30
```

Please continue to the next section "Labelling the Scale on the Plot" .

Labelling the Scale on the Plot

The plot can be labelled with the horizontal and vertical scale under the boxes area.

The scale label is made up of concatenation the text strings:

```

scale_horizontal_pre_text    horizontal scale value    scale_horizontal_post_text
and
scale_vertical_pre_text      vertical scale value        scale_vertical_post_text

```

The horizontal scale value is the value given by the scale parameter.

The vertical scale value is calculated from the horizontal scale and the vertical exaggeration for the section view.

The scales are positioned under the boxes.

scale_horizontal_pre_text	<i>text</i>
scale_horizontal_post_text	<i>text</i>
scale_horizontal_textstyle	<i>textstyle</i>
scale_horizontal_size	<i>mm</i>
scale_horizontal_colour	<i>colour</i>
scale_horizontal_x_offset	<i>mm</i>
scale_horizontal_y_offset	<i>mm</i>
scale_horizontal_decimals	<i>integer</i>
scale_vertical_pre_text	<i>text</i>
scale_vertical_post_text	<i>text</i>
scale_vertical_textstyle	<i>textstyle</i>
scale_vertical_size	<i>mm</i>
scale_vertical_colour	<i>colour</i>
scale_vertical_x_offset	<i>mm</i>
scale_vertical_y_offset	<i>mm</i>
scale_vertical_decimals	<i>integer</i>

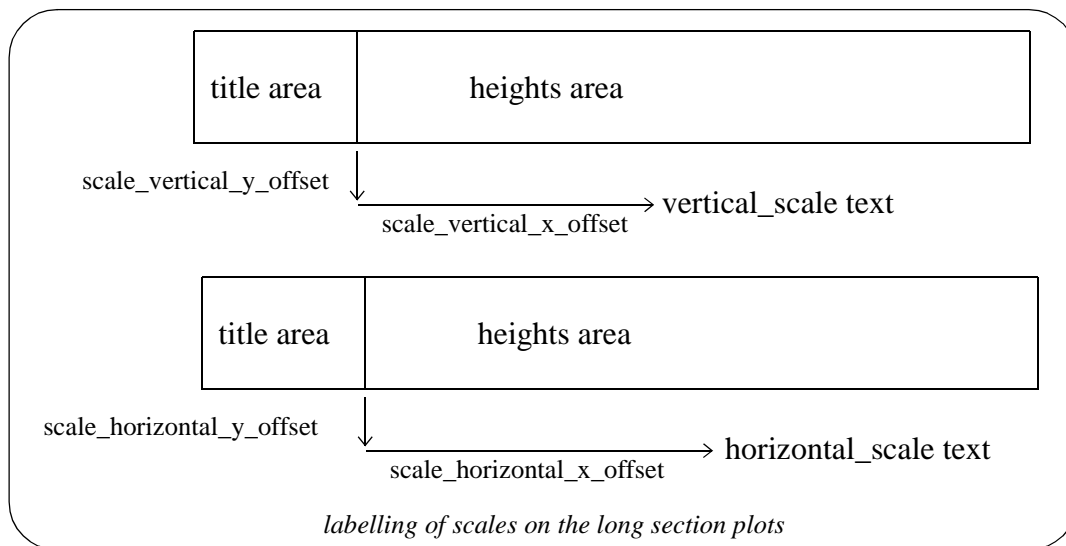

The *scale_vertical_x_offset* and *scale_horizontal_x_offset* are measured from the beginning of the heights area.

The default for *scale_vertical_x_offset* and *scale_horizontal_x_offset* are centred on the heights area.

The *scale_vertical_y_offset* and *scale_horizontal_y_offset* are measured from the bottom of the box area with positive being **down**.

If the **number of decimal places is greater than zero (> 0)**, then any trailing zeros after the decimal point are removed.

If the **number of decimal places is less than zero (< 0)**, the absolute value is taken as the number of decimal places and **no** trailing zeros after the decimal point are removed.

Example of Labelling Horizontal and Vertical Scales

scale_horizontal_pre_text	"Horizontal Scale 1:"
scale_horizontal_post_text	""
scale_horizontal_size	15
scale_horizontal_colour	yellow
scale_horizontal_y_offset	60
scale_vertical_pre_text	"Vertical Scale 1:"
scale_vertical_post_text	""
scale_vertical_size	15
scale_vertical_colour	green
scale_vertical_y_offset	90

Please continue to the next section "Title Block Information" .

Title Block Information

The plot can have a standard **12d** Model title block or a user defined title block.

The standard title block consists of a simple border around the plot and two lines of text in a box underneath the plot. For a user defined title block, all the line work and text is defined by the user.

Standard Title Block

For the standard **12d** Model title block, there are extra parameters for two lines of text and text size and colour. The standard title block is turned on or off by the parameter *plot_border*:

<i>plot_border</i>	<i>yes/no</i>	<i>// yes plots a standard title block</i> <i>// default yes</i>
<i>title_1</i>	<i>text</i>	
<i>title_2</i>	<i>text</i>	
<i>title_text_size</i>	<i>value</i>	
<i>title_colour</i>	<i>colour</i>	

User Title Block

For the user defined title block, the title block drawing commands are kept in a file whose name is supplied by the user. The title block drawing commands are almost identical to the *linestyle* drawing commands and is given at the beginning of this chapter.

Hence for a user defined title block, there are just two parameters - one to say a title block file is being used and the other to give the name of the title block file. The *plot_border* parameter should also be set to *no* so that the standard title block is not also drawn.

<i>use_title_file</i>	<i>yes/no</i>	<i>// yes draws the title block given in title_file</i> <i>// default no</i>
<i>title_file</i>	<i>filename</i>	
<i>plot_border</i>	<i>no</i>	<i>// turn off standard title block</i>

Some special plot parameters are used to pass information down to variables in a user defined title block. For example, inside the title block file it is possible to have runtime user defined text variables. The actual text values for these text variables are passed down to the title block file from the plot parameter file via the parameters *user_text_n* ($n = 1, 2, \dots, 1000$)

<i>user_text_n</i>	<i>text</i>
--------------------	-------------

The special plot parameters are:

<i>time_format</i>	<i>text</i>	<i>// format for \$time</i>
<i>user_text_n</i>	<i>text</i>	<i>// where n = 1, 2, ... 1000</i> <i>// passed down to \$user_text_n</i>
<i>title_1</i>	<i>text</i>	<i>// passed down to \$title_1</i>
<i>title_2</i>	<i>text</i>	<i>// passed down to \$title_2</i>
<i>start_page_number</i>	<i>integer</i>	<i>// used as the starting value for</i> <i>// \$page_number. If missing,</i> <i>// \$page_number starts at 1.</i>
<i>start_drawing_number</i>	<i>integer</i>	<i>// added to \$drawing_number in title</i> <i>// block file. If missing,</i> <i>// \$drawing_number starts at 1.</i>
<i>drawing_number_prefix</i>	<i>text</i>	<i>// passed down to</i> <i>// \$drawing_number_prefix</i>
<i>drawing_number_postfix</i>	<i>text</i>	<i>// passed down to</i> <i>// \$drawing_number_postfix</i>

Please continue to the next section "Parameters that Modify Fields In the Long Plot Panel".

Parameters that Modify Fields In the Long Plot Panel

A number of parameters match those in the **section long plot** panel.

When the plot parameter file is first read, any parameters in the panel will be replaced by the values of any corresponding parameters from the parameter file.

However, if the parameter is subsequently modified in the panel, the panel value will be the value used for any plots.

The plot parameters that also occur in the **section long plot** panel are:

scale	<i>value</i>
start_chainage	<i>value</i>
end_chainage	<i>value</i>
chainage_interval	<i>value</i>
chord_arc	0/1
plotter_type	<i>text</i>
plot_file	<i>text</i>
view_name	<i>text</i>
offset_model	<i>text</i>
plot_border	<i>yes/no</i>
label_depths	<i>yes/no</i>
primary_string	<i>yes/no</i>
datum_value	<i>value</i>
sheet_size	<i>text</i> or “width height”
box_text_size	<i>mm</i>
box_colour	<i>colour</i>
use_title_file	<i>yes/no</i>
title_file	<i>filename</i>
plot_border	<i>yes/no</i>
title_1	<i>text</i>
title_2	<i>text</i>
title_text_size	<i>value</i>
title_colour	<i>colour</i>
pagination	<i>yes/no</i>
pagination_length	<i>value</i>
pagination_overlap	<i>value</i>
global_textstyle	<i>textstyle</i>

Please continue to the next section “Generating Long Section Plots Without a View” .

Generating Long Section Plots Without a View

The long section plot parameters are comprehensive enough that it is possible to completely generate a long section plot without referencing a section view, or even using the **section long plot** panel.

Such a ppf can be run using the `plots=>plot a ppf` option or from the 4D Solutions programming language, 4DML.

When a long section plot is being generated entirely from a file, an extra parameter is needed to specify whether the datum value is calculated or the `datum_value` parameter is used.

```
manual_datum          1           // use the datum_value parameter for
                        // the datum
                        0           // ignore the datum_value and let
                        // 12d Model calculate the datum.
```

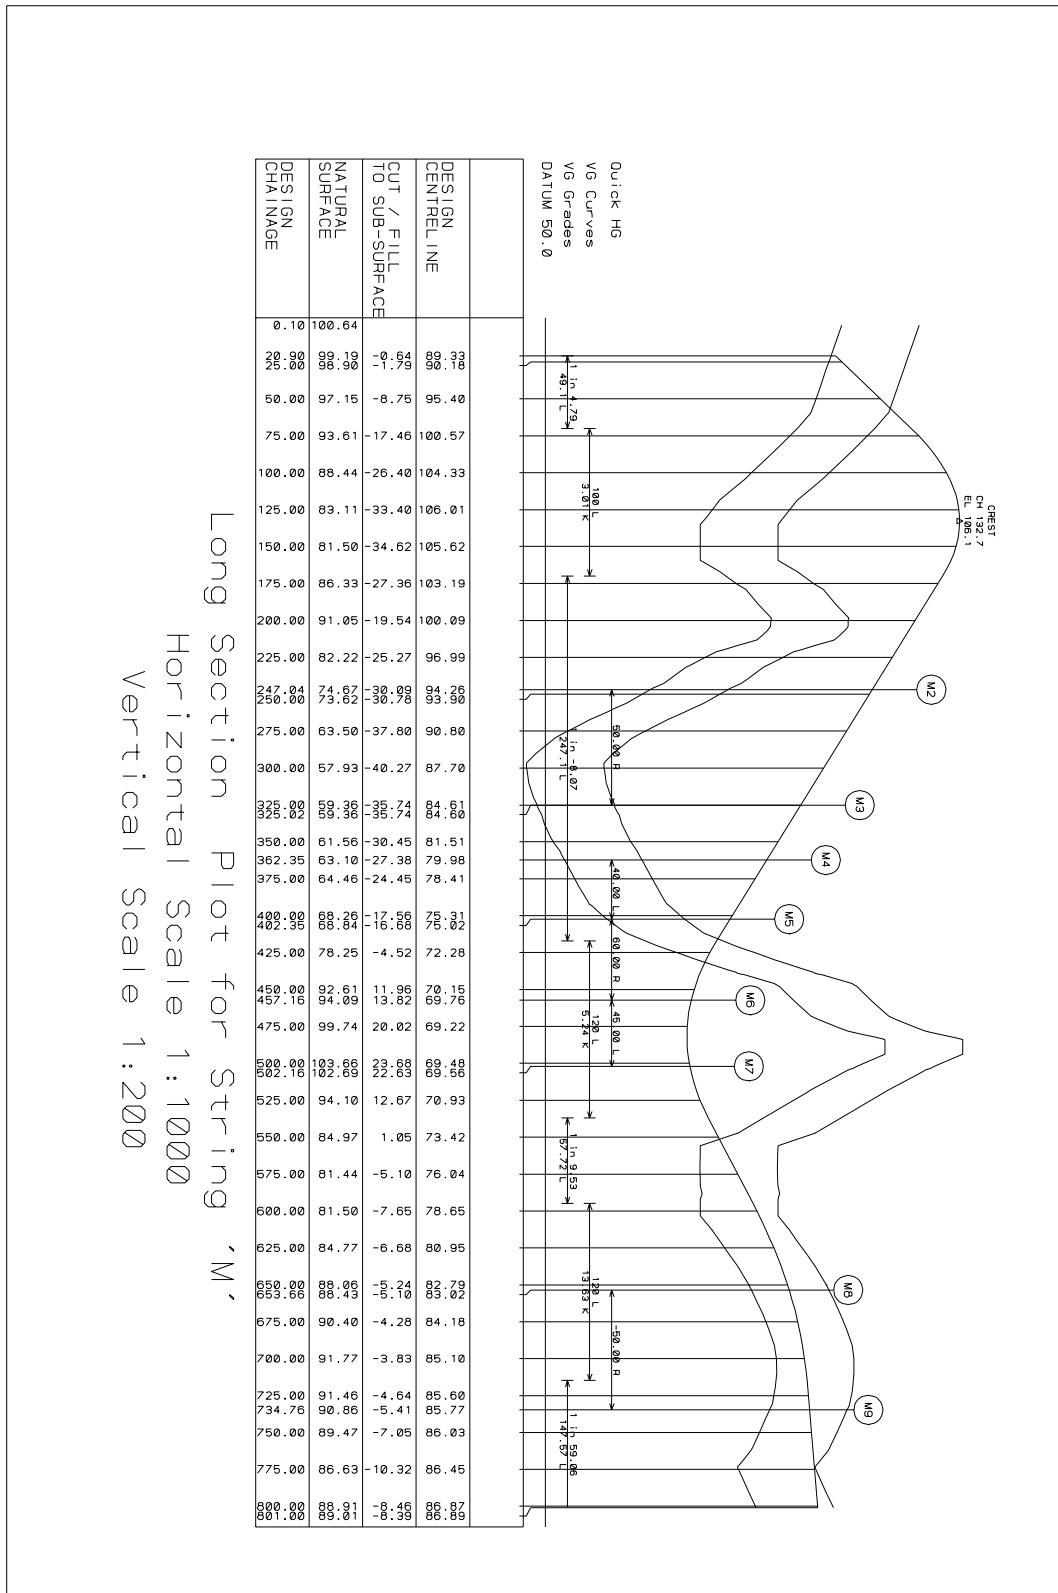

When generating a long section plot using the **section long plot** panel, a plot parameter file containing all the parameters needed to regenerate the plot using `plots=>plot a ppf` can be written out by simply giving a name for the ppf file in the plot parameters write field of the **section long plot** panel.

Notes

1. A warning is given if the keyword in a plot parameter file does not exist.
2. A warning is also given if the key word pair is defined more than once in a ppf.

Please continue to the next section “Example of a Long Section Plot Parameter File” .

#Include in Plot Parameter Files

The plot parameter file also recognizes the CCCP preprocessor rules including #include which can be used to include other files in the plot parameter file.

The format of the #include command is:

#include *file_name*

Hence a block of plot parameters can be set up in a file and included in another file using #include rather than typing them all in again.

Any number of #include's can be placed in the plot parameter file.

P Glossary

Glossary of Common Terms

Arc

Part of the circumference of a circle.

Affine Transformation 2D

A two dimensional transformation where one set of points is fitted to another. The transformation is a five parameter transformation, i.e., x displacement, y displacement, x scale factor, y scale factor and rotation. If more variables exist than degrees of freedom, i.e., more than three control points are used, a least squares solution is calculated.

AGD

Australian Geodetic Datum.

AGD66

Australian Geodetic Datum 1966.

AGD84

Australian Geodetic Datum 1984.

AMG

Australian Map Grid.

Angle, Cartesian Angle, Mathematical Angle

The angle of a point is the counter-clockwise angle from the x-axis (horizontal or East line) to the line joining the point to the origin.

The angle of a line is the counter-clockwise angle measured from the x-axis to the line.

Batter

A steeply sloping surface (usually the wall of an earth bank).

Bearing

The bearing of a point is the clockwise angle from the y-axis (vertical or North line) to the line joining the point to the origin.

The bearing of a line is the clockwise angle measured from the y-axis to the line.

Breakline

A line on a surface joining a series of points on a common change-of-grade line. For example, the ridge top or spur, top or toe of batter, creek bank. See also *tinable segment*.

Cartesian Angle

See Angle.

Chainage

Chainage is a measure of the plan length along a string. The chainage at a point on a string is the start chainage of the string plus the plan length of the string from the beginning of the string to that point.

Circular Curve

Curves defined as an arc.

Cross Fall

The lateral grade or slope of a surface (particularly of a road pavement); usually expressed as a percentage of the proportion of metres vertically to metres horizontally.

End Chainage

The chainage of the last point of a string.

Eye-Point

For a perspective view, it is the point where the observer of the perspective view looks from.

GDA

Geocentric Datum of Australia.

GDA94

Geocentric Datum of Australia 1994.

GPS

Global Positioning System.

Grade

The longitudinal slope of a surface (particularly of road pavement). Usually expressed as a cross fall percentage or as a ratio of one unit vertically to a number of units horizontally. For example, 3% or 1:10.

GRS80

Geocentric Reference System 1980.

Helmert Transformation 2D

A two dimensional transformation where one set of points is fitted to another. The transformation is a four parameter transformation, i.e., x displacement, y displacement, scale factor and rotation. If more variables exist than degrees of freedom, i.e., more than two control points are used, a least squares solution is calculated.

Hidden Line

Lines that are hidden between protruding landforms, etc. in perspective views.

Horizontal Alignment

The plan position of an alignment string (centre line) defined by intersection points, spirals and arcs.

Intersection Point (IP)

The point where two lines intersect. Usually horizontal intersection points (HIP) or vertical intersection points (VIP)

Invert

The lower inner surface of a drain or sewer pipe.

ISG

Integrated Survey Grid (NSW Australia).

MGA, MGA94

Map Grid of Australia 1994.

NTv2

National Transform Version 2. Special grid file format used in Australia, NZ and Canada for converting longitude and latitude.

Null Value

In three dimensional data, it is possible that a point can have a valid plan position but an undefined height. In 12d Model, there is a special **null** value which is used internally when height is undefined (-9.9e29).

Obvert

The upper inner surface of a drain or sewer pipe.

Parabolic Curve

Curves defined as a parabola.

Plot File

A file of plotting instructions in a format to suit a particular plotter. In 12d Model, HPGL is the default format for plot files.

Polygon

A string where the first point and the last point have the same plan co-ordinate. That is, the string closes on itself.

Screen Units

The unit of resolution for the computer screen - usually called pixels.

Shade

For a shade for a perspective view, the colour of all triangle faces are adjusted depending on the angle they make with a specified light source.

Slope

The inclination or grade of a surface or line, usually expressed as a ratio between one unit vertically to a number of units horizontally. For example, 1:10.

Snapping

A process where the element to be selected does not have to be exactly located. A tolerance is specified (the snap tolerance) and if the cursor is placed within the tolerance distance of the element then the cursor is moved directly ("snaps") to the element.

Different snap settings determine what parts of the element are considered for snapping to. For example, points on the string (point snap), drop perpendicular on the lines of an element (line snap) and grid points (grid snap).

Spiral

The special type of curve used for transitioning between straights and arcs in an alignment string (centre line). Also known as a transition curve or transition spiral.

Start Chainage

The chainage of the first point of a string.

String

A string is an ordered series of points.

Apart from the first and last point in a string, each point in a string has a unique next point (successor) and a unique previous point (predecessor). The previous and next points for a point are called its string neighbours. The lines joining a point with its neighbours are called string links.

A string which has the same first and last point is called a closed string otherwise a string is said to be open.

Strings are very useful in the modelling of terrain and design surfaces. 12d Model uses a number of different **types** of strings which as defined in the chapter **Tools and Concepts**.

Sweep Angle

For an arc, the sweep angle is the angle, measured in the **clockwise** direction, between the line joining the arc start point to the arc centre and the line joining the arc end point to the arc centre.

Tangent Point

A point at which a curve touches a line or another curve such that the tangent vector at that point is the same for the two touching items.

Target-Point

For a perspective view, it is the point that the observer is looking at.

Template

Standardized cross-section which is applied to a string at defined chainage points.

Template Modifiers

12d Model commands which modify the definition of a template. Template modifiers are used in preference to defining hundreds of different templates.

TIN

Triangulated Irregular Network. A TIN is a set of triangles which do not non-overlap in plan. Each vertex of a triangle has a z-value so that the TIN represents a surface in three dimensional space made up of triangular faces. When a TIN is created from a data set, the triangles are formed so that all non-null points are vertices of triangles. If breaklines are preserved in the TIN, then triangles are constrained so that any link from a breakline string is a side of a triangle.

Tinable vertex or point

If a vertex or point is tinable, then the vertex/point is included in triangulations. If the vertex/point is not tinable, then the vertex/point is ignored when triangulating.

Tinable segment or line

If a segment or line is tinable (and both the vertices at the ends of the segment/line are tinable and the z-values not null), then the segment/line is used as a side of a triangle during triangulation. This may not be possible if there are *crossing* tinable segments/lines.

A tinable segment is also known as a *breakline*.

Note that for a segment/line to be used as a side of a triangle, then its end vertices must be tinable and the z-values not null.

Triangulation

A set triangles, which do not overlap in a plan view, created from a set of data points. See TIN.

UTM

Universal Transverse Mercator.

View

The area in **12d** Model used for displaying (drawing) graphical information. In **12d** Model there are three types of views - plan, section and perspective.

Vertical Alignment

The long section position of an alignment string (centre line) defined by vertical intersection points (VIP's) and parabolic or circular curves.

WGS84

World Geodetic System 1984.

World Units

The fundamental units used in 12d Model - usually metres.
